1905

TO MY
MANY GENEROUS AMERICAN FRIENDS
FRIENDS AS GENEROUS IN THEIR HOSPITALITY
TO THE STRANGER
AND THEIR APPRECIATION OF HIS DIFFIDENT SERVICE
AS IN THEIR LOVE OF LEARNING
THIS TRACT IS DEDICATED

S. FRANCISCO, 1898.

ST. LOUIS, 1904.

PREFACE

IN Inner medicine, as in all the other departments of the Congress at St. Louis, two addresses were proposed—the first to deal with the outward relations of the subject, the second with its internal problems. My colleague, Dr. Thayer, was so good as to commit to me the outward relations, as in this respect I had some materials already in hand. In recent times the relations of medicine and surgery have become so complex, and in certain directions are still so perverse, that I have preferred to deal with them at their sources, and in their earlier and simpler connexions and contrasts; that is, in ancient and medieval times. In the times of Greece and Alexandria medicine and surgery were one; to the clear eye of the Greek they could not be sundered: in medieval times on the other hand new and vaster social constructions, new and more conflicting conditions, compelled our fathers to build in their eagerness on a narrow and temporary framework.

The analytic historian lays bare the Middle Ages of Europe; he goes to the sources, he works up his

descriptions, and we think we are learning something of that wonderful time until we drop *pièces justificatives* for the *Canterbury Tales*, and the drone of the lecture-room for the clarion of St. Bernard, or perchance wander into one of its minsters during the *Benedicite* or the *De profundis*, and start almost with fear to discover that their deeper and richer possession seems farther from us than ever. While we were repainting their pageants, deploring their furies, refuting their dialectics, it is suddenly revealed to us that to refute the conceptions of medieval thinkers is not to explain the origin of their ideas, and that beside their vision and their passion our hearts have grown cold and slow. To the Middle Ages we may adapt the fine thought of Burke that "dark confused uncertain images have a greater power to form the grander passions than those have which are more clear and determinate." And as to our modern civilities, have not these new islanders of the Pacific put them all on before our eyes, in a few months as it were; and dressed them even better than we have done! Still in our way we must on, anatomising the Middle Ages and searching for the lost key of their lyrical secret, that peradventure by dismembering the body we may reach its soul. Or is it rather by chemistry that we may extract this essence? Is it by weighing the spirit of Ionia, the spirit of Rome, the spirit

of Byzantium, the spirit of Cordova, that we shall capture the essence of Chartres, of Fulda, of Paris, of Bologna, of Florence? One spirit, indeed, glows through all their magic, a fire never utterly extinct, the spirit of ancient Greece—of Ionia, Athens, and Greek Italy, and so of all Italy, penetrating the alien hearts of Jew and Syrian, of Gaul and Spaniard, of Frank and Teuton, and revealing to all the wonder and beauty in common things.

As we cannot know any part of an age or people without an idea of the whole, nor take to ourselves a lesson from other times and other folk without some conception of their nature and fashion, so we cannot know modern Medicine unless we study it as a whole, in the past as well as in the present. From Greece and medieval Italy we have to bring home the lesson that our division of Medicine¹ into medicine and surgery had its root not in nature, nor even in natural artifice, but in clerical feudal and humanistic conceits. “*Quae enim in natura fundata sunt crescent et augeantur; quae autem in opinione variantur non augentur.*”

If we inquire more closely how Medicine fared in the fiery youth of modern Europe, we may offer at any rate two parts of the answer: first, the iron rule of prince and prelate, wicked as individual

¹ In this essay I have written “Medicine” (with capital initial) to signify our profession as a whole; and “medicine” (with small initial) to signify “Inner medicine,” as divided from surgery and obstetrics.

rulers have been, was possible because the peoples felt instinctively the radical and universal need of the age to be that the elements of the new Europe should be welded into a stable and coherent whole. This passionate idea of unity, called now the Church, now the Empire; here visible as the feudal tramp of the crusades, there as the tyrannous vociferations of the schools, would brook no schism, ecclesiastical social or personal. As of every other sphere, so this spirit of domination took possession of Medicine, and therein set up the idolatry of Galen as inexorably as that of Aristotle in the sphere of philosophy. Whatever at one period were the constructive effects of this despotism, when it had outlasted its time it became as oppressive to Medicine, and to all knowledge, as formerly it had been socially integrative.

Secondly—or indeed it is another aspect of these reflections—the soul of the Middle Ages was a collective soul; its great works were the offspring not of individuals but of peoples. Who built the minsters, who painted the windows and the Books of Hours, who wrote the liturgies and chansons, we know not. As the churches, the liturgies, the manuscripts, the poetry and drama were achievements not so much of persons as of congregations, so also medieval learning was for the most part the learning of inspired crowds at the heels of a rhetorician.

Thus all this medieval achievement, fervid and

beautiful as it was, could not do much for science ; nor even for the intellectual harmonies of the fine arts. As the medieval spirit was multiform and catholic, the Greek spirit on the contrary was choice and personal, and owed its being to individuals—to Ictinus and Mnesicles, Phidias and Polygnotus, Homer and Aeschylus, Plato and Aristotle, Mantegna and Donatello. The Greek was an individualising and an emancipating spirit, the medieval collective and enthralling—a genius of assemblies and associations of men. It was by strife of individuals for personal development that through much suffering Greek thought and the personal life was reawakened ; and until this emancipation scientific research and intellectual art were impossible or ineffectual. In art the finer harmonies of form and the conscious appreciations of the personal artist were not medieval but Greek ; likewise in science the spirit of individual research and the freedom of individual opinion were impossible under the oppressions and the checks of collective despotisms. In this cause of the individual against society, if Luther and Knox were triumphant Dolet and Bruno were burned, Galileo and Palissy were spared reluctantly. It is interesting to reflect however that as in Italy a sense of unity never died away, even in medieval times, so in this land the need of a compulsive uniformity was less passionately felt ;

and, until the ascent of the malignant star of Spain, a larger life was open to the sciences and to Medicine, especially in the free cities of Florence and Venice. But in France a new nation had to be forged out of conflicting and reluctant elements ; and therefore till consolidation was achieved the framework of custom had to be as rigid as steel. Thus in Paris Medicine, like other energies, was far more rigidly fixed by sacerdotal scholastic and military convention than in Italy ; in Paris the inflexible rule of privilege strangled all quickening in science and stiffened its professors into obsequious automatons.

To the student of Greek Medicine the separation in later times of surgery from medicine, which cut most deeply in Paris, seems as false in notion as in practice it has been pernicious. If the modern surgeon is vexed to hear that surgery is, as Galen declared, but a method of treatment, he is vexed by a truth which in the best interests of our profession he ought to welcome. That in later ages in Europe the field of surgery has been avoided by the "physician," and the field of medicine forbidden to the surgeon, and that by this unnatural schism Medicine has suffered much bane, is illustrated in history, as it is day by day in the fragmentation of our work. For example, a few weeks ago an able surgeon wrote—and so far as I read him—in no ironical mood: "Let

us realise that the cæcum in these cases is the physician's, and the appendix the surgeon's. . . . This would make an honourable draw of the tug-of-war." In the next paragraph he wrote: "Those cases which apparently do not get well after an affected appendix has been removed have only themselves and the physician to blame . . . when the surgeon has done his share." What a mockery for the physician no doubt the shrewd surgeon knew well enough. Another surgeon demurely writes: "Here I am afraid to go on lest I should trench upon the subject of medicine." Professor Penzoldt more frankly laments the evil of the factitious division of practice into medicine and surgery, and sees no compensation for its disadvantages. How ungracious a part all this is for the surgeon, how hollow a part for the physician, how inconvenient, mischievous and adverse to the organisation of our science and art it is my purpose to enforce. How many years have we lost in such maladies as infantile palsy, diseases of the stomach, diseases of the pelvis, and so forth, because surgeons pretend to be "afraid to trench upon" a large and essential part of their own pursuit, and because physicians have been brought up in unhandy ways.

It will not be supposed that I ignore the limits and diversities of human faculty, for to one may be given manual dexterity, to another sagacity of observation and inference; nor forget the field of

Medicine is so vast that for the narrowness of man's capacity it must be divided: what I urge is that the limits should be by personal choice on natural lines, not by the survival of medieval rules, even in their own day vicious, whereby we have made an idol of this divergence, telling each physician, each surgeon, that he shall not follow the bent and growth of his own faculties and the intimate tracks of nature, but that, whatever his capacities and occasions, thus far he shall go and no farther; in the use of his natural gifts he shall be fettered by an artificial rule. Every wise man learns, but too soon, his own defects, his own limits, his own bents, and the natural economy which they impose upon him; but to maintain separate Colleges to intensify schism, to separate the man who treats a disease with one remedy from the man who treats the same disease with another remedy, to distribute half of a malady to one practitioner, to another the remnant, to encourage in the surgeon a show of ignorance of one portion of a disease which he has to treat, and the pretence of taking this at second hand from another, to prescribe to the physician that he may carry a merely inferential knowledge of a disease to the utmost, but shall not occupy himself with the directest way of ascertaining its intimate nature, and perhaps the only way of curing it, is contrary to nature, art and common-sense. Surely the hour has come to amalgamate medical institu-

tions and customs, to establish an Academy of Medicine every member of which shall be free to develop his faculties in whatsoever honourable paths they may lead him, and formally to recognise an integration which, in spite of custom, in ophthalmology, dermatology, gynæcology, has established itself before our eyes. In diseases of the abdomen shall we continue to hamper and confine the disciples of Hippocrates, Linacre, and Harvey in the study of the anatomy of the living disease which is the privilege of their brethren who own allegiance to Hippocrates, Paré, and Hunter? In cerebral surgery for instance is it not absurd for one institution to deny, let us say, to Sir William Gowers and Professor Ferrier a liberty which by another institution is granted, let us say, to Professors M'Ewen and Horsley?

It is unnecessary to carry on this argument into the diseases of the stomach, of the peritoneum, of the gall-bladder, of the pancreas, and so forth, where the surgeon, besides his peculiar advantages, has all that liberty of inferential methods with which alone the physician has perforce to content himself. Does not the physician see how treacherous is the bottom of this alliance; how rapidly the surgeon is not only attaining "medical" sagacity but, every day correcting sagacity in the laboratory of living processes, is even in security and precision of diagnosis coming to surpass the mere physician?

Moreover—to pass to higher considerations—the habit of dwelling rather in appearance than in realities is, as Acton said, the habit of regarding the report rather than the bullet and the echo rather than the report. Let us take for our new Academy the Wriothesley motto: “*Ung par tout et tout par ung.*”

In writing of ancient authors I have preferred familiar use to scientific orthography. Nothing does more to make history unreal than to give men pedantic names, or names which to us seem uncouth. As Horace, Avicenna, Tintoret are of “our business and bosoms,” so are Galen, Salicet, Guy; on the other hand to write John Kaye for “Caius” would be as pedantic as to substitute Albert the Great for Albertus Magnus, or von Hohenheim for Paracelsus. In doubtful instances however it is best to prefer the less exotic forms.

In conclusion I would thank my colleague Professor Howard Marsh for his charity in perusing my proofs; but I scarcely know how to do this as I ought without seeming to lay upon him some portion of a responsibility which I must bear alone.

T. C. A.

THE HISTORICAL RELATIONS

OF

MEDICINE AND SURGERY

It was I think in the year 1864, when I was a novice in the Honorary Staff of the Leeds General Infirmary, that the unsurgical division of us was summoned in great solemnity to discuss a method of administration of drugs by means of a needle. This method having obtained some vogue, it behoved those who practised "pure" medicine to decide whether the operation were consistent with the traditions of purity. For my part I answered that the method had come up early, if not originally, in St. George's Hospital, and in the hands of a House Physician—Dr. C. Hunter; that I had accustomed myself already to the practice, and proposed to continue it; moreover that I had recently come from the classes of Professor Trousseau who, when his cases demanded such treatment, did not hesitate himself to perform paracentesis of the pleura, or even incision of this sac, or of the pericardium. As, for lack not of will but of skill and nerve, I did not

B

2 THE HISTORICAL RELATIONS

intend myself to perform even minor operations, my heresy, as one in thought only, was indulgently ignored, and we were set free to manipulate the drug needle, if we felt disposed to this humble service. About this time, when indeed few Fellows of the London College of Physicians would condescend even to a digital examination of rectum or uterus, certain of them, concerned with the diseases of women, began to make little operations about the uterus; and, meeting after all with but slight rebuke, they rode on the tide of science and circumstance, encroaching farther and farther, until they were discovered in the act of laparotomy, and, rather in defiance than by conversion of the prevailing sentiment of that Corporation, they went on doing it.

Meanwhile the surgeons, emboldened by great events in their mystery, wrought much evil to the "pure" physicians; accusing them with some asperity of dawdling with cases of ileus and the like until the opportunity of efficient treatment had passed away: nay, audacious murmurs arose that such "abdominal cases" should be admitted into the surgical wards from the first. Then by dexterous cures growing bolder and bolder the surgeons went so far as to make a like demand for cases of tuberculous peritonitis, of empyema, and even of cerebral tumour. As thus the surgeons laid hands on organ after organ which hitherto had been sacred to "pure" medicine, and indeed as the achievements of surgery became more and more glorious, not only the man in the street but the

man of the Hospital Committee also began to tattle about the progress of surgery and the diminution of medicine, until it was only by the natural sweetness of our tempers that the surgeon and the inner mediciner kept friends. At a dinner given on the 30th of June last to Mr. Chamberlain, in recognition of his great services to tropical medicine, this eminent statesman said, "I have often heard that while surgery has made gigantic progress during the last generation, medical science has not advanced in equal proportion"; then, while modestly disclaiming the knowledge to "distinguish between the respective claims of these two great professions," he generously testified that "medical research assisted by surgical science has thrown a flood of light on the origin of disease, and that this at any rate is the first step to the cure of disease." Now Mr. Chamberlain is the first of English statesmen to ally himself actively with our profession, the first with imagination enough to apprehend the great part which medical science is playing in the world already, and to realise that only by medicine can vast surfaces of the earth be made habitable by white men, and those "great assets of civilisation," the officers of our colonies, be saved alive. It seems to me then that the present is a critical moment in the relations of medicine and surgery, especially in England where the two branches of the art have been so radically separated as to be regarded as "two professions"; a moment when it is our duty to contemplate the unity of Medicine, to forecast its development as a connected whole, and to conceive

4 THE HISTORICAL RELATIONS

a rational ideal of its means and ends. But this large and prophetic vision of Medicine we cannot attain without a thoughtful study of its past.

If thus, as from a height, we contemplate the story of the world, not its pageants, for in their splendour our eyes are dimmed, but the gathering, propagation and ordination of its forces, whence they sprang, and how they blend this way and that to build the institutions of men, we wonder at their creative energy, or weep over the errors and the failures, the spoliation and the decay, which have marred or thwarted them; and if we contemplate not the whole but some part of men's sowing and men's harvest, such as Medicine, the intenser is our sorrow and disappointment, or our joy and hope, as we admire the great ends we have gained, or dwell upon the loss and suffering which have darkened the way. In the development of Medicine said Helmholtz, "there lies a great lesson on the true principles of scientific progress."¹

Pray do not fear however lest, to fulfil the meaning of the title of this address, I should describe to you the history of medicine, and the history of surgery, and on this double line compare and combine my researches; in the time allotted to me no such survey is possible. I can but select certain eminent features of the histories of these departments of knowledge, and compare them with a view to edification; your fear may be rather lest I should

¹ ("Es liegt eine grosse Lehre über die wahren Prinzipien wissenschaftlicher Forschung in dem Entwicklungsgange der Medizin.")

dress an arbitrary story with the unrighteousness of a man with a moral.

In his address on Morgagni, at Rome in 1894, Virchow said that Medicine is remarkable in its unbroken development for twenty-five centuries; as we may say without irreverence, from Hippocrates to Virchow himself. However the great pathologist's opinion seems to need severe qualification; if so it be, the stream has more than once flowed long underground. The discontinuity of Medicine from Egypt to Crotona and Ionia is even greater than from Galen to Avicenna, a period during which, in spite of a few eminent physicians in the Byzantine Empire, it sank into a sterile and superstitious routine.

Classical medicine, the medicine of the fifth century B.C., is represented for us by the great monument of the scriptures collected under the name of the foremost teacher of his age, Hippocrates; in genius perhaps the greatest physician of all past time. The treatises of the Canon may be divided into medicine, surgery, and obstetrics. The medical treatises, when read in an historical spirit, command our reverent admiration. Written at a time when an inductive physiology was out of reach, we are impressed nevertheless by their broad, rational, and almost scientific spirit. Medicine, even when not dominated by contemporary philosophy, has always taken its colour from it; and the working physiology of Hippocrates was that humoral doctrine, originally derived from

Egypt and the East, which, as enlarged by Galen, ruled over medicine till recent times. That in later ages it became the engine of a fantastic and tyrannous dogmatism we know but too well; how was it then that Hippocrates and his school were so little perverted by it? To pretend that it had no such effect, or that the speculative schools of Greece swept over medicine without perverting it, would be idle. Hippocrates, while distinguishing between the methods of outward and inward maladies (*φανερὰ καὶ ἄδηλα νοσήματα*), taught that even for the inner many facts are accessible to methodical investigation, by careful sight and touch, laborious inspection of excretions and so forth; yet as in these diseases the field of inference is much larger than in the outward, the data even of direct observation fell the more readily into the scheme of the four humours, and by this doctrine were so coloured that, although noted and pondered with rare clinical insight, they were read into the scheme of a fictitious pathology.

How was it then, I repeat, that the speculative side of the medicine of the period bewildered Hippocrates so little? Because in the first instance the clinical method of the school was broadly and soundly based upon the outward maladies. No sooner did an internal affection—empyema for example—work outwards than the mastery of Hippocrates became manifest. What we moderns separate as surgery, surgery which from Galen to Paré, by Clerks, Faculties and Humanists, was despised as vile, and from Paré to Hunter as

illiberal, was in the age of Hippocrates, as in all epochs of medicine since that age, its saviour. By his surgery it was that Hippocrates was led to announce clearly and categorically the first principles of inductive research and practice; namely, phenomena first, then judgment, then general propositions, then practical knowledge and craft. One principle only, but that a great one, was wanting to him, namely, experimental verification; a principle not definitely apprehended by Aristotle, nor by any ancient physician except Galen.

If our admiration of the inner medicine of Hippocrates, great as it is, is a relative admiration, an admiration of the historical sense, of his outer medicine our admiration is immediate and unqualified. Little as the fifth century knew of inward anatomy, as compared with Alexandria about two centuries later, yet the marvellous eye and touch of the Greek physician had made an anatomy of palpable parts—a clinical anatomy—sufficient to establish a Medicine of such parts of the body of which our own generation would not be ashamed. That this acuteness of the “cerebral” as well as of the “retinal eye,” was a note of the time, is illustrated by the observation, by Professor Waldstein, in sculpture of this period, of a certain muscle of the groin, especially developed no doubt by Greek athletics, which in its now diminished form had escaped the eyes of modern anatomists.

In respect of fractures and luxations of the forearm M. Pétrequin pronounces Hippocrates more complete than Boyer; in respect of congenital

luxations richer than Dupuytren. Malgaigne again admires his comparison of the effects of unreduced luxations on the bones, muscles, and functions of the limb, in adults, in young children, and before birth, as a wonderful piece of clinics. In Littré's judgment the work of Hippocrates on the joints is a work for all time. In gibbous spine he distinguishes the traumatic kind from that of internal origin; and points out that in this case tubercles are often found in the lungs and mediastinum, and may indeed by extension be the direct cause of the spinal affection; a doctrine accepted by Galen, and then forgotten till it was recalled by Zachary Platner early in the eighteenth century, and re-established by Delpech in the second half of the nineteenth. Hippocrates chides those blunderers who take a spinal apophysis for the body of the vertebra, or the internal tubercle of the humerus for a part of the forearm. On wounds, which in warlike and unruly ages have constituted a principal branch of surgery, Littré pronounces that the Hippocratic books must be studied with deep attention; for they are founded on a wide experience, minute and profound observation, and an enlightened and infinitely cautious judgment. In the handling of wounds the surgeons of the Hippocratic school were indeed, as we shall see presently, far better instructed than the surgeons of the mediæval and renaissance periods. If poultices were used they were applied near but not upon the wound; the water for washing the wounds, unless very pure, was filtered and boiled; their linen dress-

ings were of new material, and the hands and nails of the operator were cleansed. Of the access of air to the wound the Greeks were very jealous, a jealousy which in later times led to abuse of the suture. Their local medications were wine and oil, with some excess in oil; greasy applications, or salves, became the curse of later surgery. In fresh wounds healing by first intention was expected, though in less recent and in contused wounds suppuration was anticipated. To foul wounds certain balsams were applied. Wound-fever was known to the school, and the different significance of fever in the first week and in later weeks was pointed out. Puerperal fever was interpreted as a wound-fever, and its occasional origin in retention of putrid uterine contents was recognised. In wounds of the head Hippocrates warns against careless interference with the temporal regions, lest convulsions and palsy occur on the opposite side of the body; for the trepan was then in vogue, as it had been from the darkest backward of time. In spinal injury he notes that incontinence of urine and faeces is of fatal augury. From amputation of the larger limbs he flinched, as did most if not all responsible surgeons down to Paré; for inner anatomy was ill-known, and ligature of arteries, even in wounds, made slow way: indeed before Celsus this method seems to have been unknown. Caries was not definitely distinguished from necrosis; but a case of disease of the palate with fallen nose irresistibly suggests syphilis. On eye diseases we find much of interest, though the

media were imperfectly distinguished, and the seat of cataract was undetected. Nyctalopia however was recognised; and relief was given by operation for such diseases as ectropion, hypopyon, and the like. Of obstetrical practice, I must be content to say that it had reached a high standard; when surgery flourishes obstetrics flourish. By the very wealth of knowledge in these treatises indeed we realise that the Father of Medicine stood in the line of a noble ancestry; and that by his genius and leadership what I may call a great Paradosis received a permanent form.

It is by comparison of one part of the Hippocratic Canon with another that we learn how a strong grasp of inner medicine was attained by way of severe discipline on its positive or surgical side. And this not by mere empiricism; it may well have been from Hippocrates himself that Aristotle learned how by empiricism (*ἐμπειρία*) we perceive a certain remedy to be good for this person or for that—for Socrates, let us say, or for Callias—when he has a certain fever; but by reason we discover the characteristic common to these particular persons whereby they react alike. In his Book of Precepts Hippocrates tells us that *τριβὴ μετὰ λόγου* is the basis of all medical knowledge. Now *τριβή* is primarily a grinding or rubbing; so the student must rub and grind at nature, using his reason at the same time: but his reason must be a perceptive and interpretative, not a productive faculty; for he who lends himself to plausible ratiocination (*λογισμῶπιθανῶ προσέχων*) will find himself ere long in a

blind alley ; and those who have pursued this course have done no credit to Medicine. How soundly, for the time, this lesson was learned we see in the theoretical appreciation of these several faculties in the first chapter of the *Metaphysics*, and in the Sixth Book of the *Ethics*, where the senses, it is urged, cannot really be separated from the mind ; for, as St. Thomas forcibly reiterated, the senses and the mind contribute each an element to every knowledge.¹ I would venture to suggest that this method of observation, experience, and judgment was established in Medicine first, because Medicine of all arts is the most practical and imperative ; and, as Aristotle says, is concerned with the individual patient : thus to our art may belong the honour of the first application of positive methods to all subjects of natural knowledge.

The chief lesson of the Hippocratic period for us is that, in practice as in honour, medicine and surgery were then one. The Greek physician had no more scruple in using his hands in the service of his brains than had Pheidias or Archimedes ; and it was by this co-operation that in the fifth century an advance was achieved which in our eyes is marvellous. As we pursue the history of medicine in later times we shall see the error, the blindness, and even the degradation of the physicians who neglected and despised a great handicraft. To the clear eyes of the ancient Greeks an art was not liberal or illiberal by its manipulations but by its ends. As because of its ends the cleansing and

¹ Compare also the last chapter of the *Posterior Analytics*.

solace of the lepers by St. Basil, St. Francis and Father Damien was a service of angels, so Hippocrates saw no baseness even in manipulations which obtained for his followers the name of *coprophagi*: where there is no overcoming there is no victory.

Between Hippocrates and Galen, an interval of some five centuries, flourished the great anatomical and medical schools of Alexandria. Our only important source however for the medicine of the Alexandrian period is Celsus, who lived in the reign of Augustus. From Celsus we infer indeed that the brilliant anatomy of Alexandria made for good practice in surgery, and for surgical diagnosis; yet the influence seems not to have been so direct and effective as might be supposed. Haeser argues indeed that too intense a devotion to healing as a craft prevented the healer from thinking anatomically. As regards the Empirical School this may be true; for by it not only was systematic thinking discouraged, but ancillary science was regarded also as vain, if not mischievous. Its spokesman Serapion protested, against the great anatomists, that in Medicine observation and record are all-sufficient. This was to look at nature indeed, but with the many faceted eye of the insect. No doubt with the exception of anatomy the ancillary sciences were in a vaporous condition, and to the hardihood of the empirics, narrow as it was, medicine owed much. Still, as facts will return in ever new combinations they must provisionally be interpreted by analogy; that is, by the application of universals from one sphere

to another. Thus in *Airs, Waters, and Places* analogy was safer for Hippocrates than a rudimentary geography and meteorology, and, as is notable in his school, it did good service in prognosis; yet analogy is so facile an instrument that even in the school of Hippocrates the temptation to use it became too strong and too general. Inductive in spirit analogy may be, as even Serapion (in his "*ἡ τοῦ ὁμοίου μετάβασις*") admitted; but it lends itself very freely to airy and even to metaphysical hypotheses, wares which can be turned out in satisfactory profusion without that *πέτρα τριβική*—that grinding and rubbing in nature—on which Hippocrates insisted. For the solid work of surgery and midwifery, however, such fabrics are too flimsy; they find their market in inner medicine, a domain in which, as surgeons in all times have been wont to complain, our failures are covered up and buried.

Nevertheless in the VIIth and VIIIth Books of Celsus we see that surgery and midwifery had made substantial progress since Hippocrates, and probably since the Alexandrine School of Erasistratus and Herophilus. Celsus, probably not himself a practitioner,¹ is rather vague in detail: still,

¹ In deference to the opinion of the last editors of Celsus, Angiolo and Isidoro Del Lungo, who opine that Celsus was himself formally a practitioner of Medicine, I changed the "probably not" of my manuscript into "perhaps not." But on further consideration of the arguments of the Del Lungos I have returned to "probably not." What Scaliger and Casaubon thought may on this point have little weight with us; that Morgagni regarded Celsus as a practising physician has no doubt far more. Still Daremberg [the standard Latin text is that of Daremberg (Leipzig, 1859)], Pidoux, Broca, Védrenes, have decided otherwise; and although I cannot set my superficial impressions of this author beside the ripe studies of Angiolo Del Lungo, yet I cannot help coming also to

besides the Hippocratic surgery, we recognise means of treatment in piles, fistula, rodent ulcer, eczema, fractures, and luxations; missiles were removed from their wounds; tumours—of which surgeons before and after were afraid—were excised; the nasal passages were cauterised for ozæna; dropsies were systematically tapped; hernias were submitted to radical cure; genito-urinary diseases were attacked in both sexes; his operation for stone, as we shall see, held the field till Malgaigne and Cheselden; plastic operations were undertaken; arteries were tied, and, for the first time, the larger limbs were deliberately amputated—though only in extreme need, and often with fatal results by secondary hæmorrhage and otherwise. His wound surgery was Hippocratic (p. 8), and he warns the surgeon, in his anxiety to exclude the air, not to use the suture until the depth of the wound has been so cleansed that no clot remains, for this turns into pus, excites inflammation and prevents union. These chapters signify a large accumulation of experience on a positive method, which can hardly be predicated of the inner medicine of the period.¹

the opinion that in some places Celsus speaks as a physician would hardly have spoken, and in other and not a few places omits, to one's vexation, those intimate details which a practical man would surely have made a point of. And how strange it is that no one of the physicians of the later Empire—Greek physicians, it is true, but again that neither Pliny nor Quintilian—alludes to Celsus as a practitioner; strangely inconsistent as this calling would have been with the prejudices of his class in Rome. Furthermore, we know that Celsus wrote “non sine cultu et nitore” (Quintilian) like treatises on agriculture, rhetoric, law, philosophy, and the art of war. Celsus, it would seem, preceded Robert Pullen and Brunetto Latini as an encyclopedist. After all the matter is not worth much ink.

¹ Recent excavations have yielded a rich collection of surgical

How active surgery was from Celsus to Galen, and how honourable and progressive a part of Medicine, we know from the scanty records handed down to us in the compilations of Oribasius and other authors. From the remnants of the writings of Heliodorus we gather many things; among others that amputation was resorted to in comminuted fracture—*e.g.* of the leg below the knee—before gangrene actually set in; moreover that the operation was very carefully performed, including the preparation of some sort of flaps. Archigenes of Apamea also practised in Rome, in the reign of Trajan. Galen calls him an acute but too subtle a physician; such of his subtilities as are known to us however—his distinction between primary and consequential symptoms for instance—are to his credit. He applied the ligature in amputations; and that remarkable man Antyllus, who unfortunately is known to us only in Oribasius and his copyist Paul,¹ applied the method to the cure of aneurysm, which however Rufus seems to have done before him. Galen tells us where he got his “Celtic linen thread” for the purpose, namely “at a shop in the Via Sacra between the Temple of Rome and the Forum”: a shop near his own house, which was instruments which are a vivid illustration of the ingenious and methodical surgery of the Roman Empire. In his edition of Celsus M. Védrenes publishes plates of these, and uses them aptly in the interpretation of the author.

¹ That Paul in the seventh century may have had direct access to extant works of Antyllus is possible; but the manner of his citation is that of a copyist, and in matter coincides with the selections of Oribasius. I ought to say that Haeser gives Paul more credit for originality than I am yet able to do.

also in the Via Sacra, by the Temple of Peace. We learn also, from Oribasius, that Antyllus practised extensive resections of bone in the limbs, and even in the upper and lower jaw. Much excellent surgery, of which I cannot now speak in detail, disappeared in the chaos of the Dark Ages.

Galen came to Rome under Marcus Aurelius. In the biological sciences this great physician stands to Harvey as in physics Archimedes stood to another great physician, William Gilbert; Galen was the first, as for many centuries he was the last, to apply the experimental method to physiology. He embraced the ancillary sciences; he opened out new routes and he improved the old. Unhappily his soaring genius took delight also in the spheres of speculation; and it was not the breadth of his science nor the depth of his methodical experiment, but the height of his visionary conceits which imposed upon the Middle Ages. Galen did not himself forget the precept of Hippocrates—To look, to touch, to hear (“*καὶ ἰδεῖν, καὶ θιγεῖν, καὶ ἀκούσαι*”); but he did not wholly subdue himself to the *πεῖρα τριβική*—this toilsome conversation with troublesome facts. For example; in a pseudo-galenist treatise, but one which fairly represents what we know of Galen’s doctrines,¹ we read . . . “*προηγείται δὲ τῆς πράξεως ἢ θεωρίας . . . ἀρχὴ γὰρ τῆς ἐπὶ τῶν ἔργων τριβῆς ἢ διὰ τοῦ λόγου διδασκαλία.*” Nay, possessed by platonist visions, enamoured of an

¹ *Definitiones medicae*, Ed. Kühn, xix. 351. Palissy said his proofs were “*la vue, l’ouye et l’attouchement.*”

elaborate teleology of his own, and in violent reaction against the Empirics, he formulated an eclectic doctrine contrary to the experimental reason (*τριβὴ μετὰ λόγου*); and taught categorically that speculation shall guide experience. So it was that he imposed philosophical lectures upon students as preliminary to medical study, carried speculation into his physiological experiments and even into anatomy itself, gave a subjective cast to his finest work, and foisted metaphysics in another guise on medicine. Galen did not make any great mark on surgery. He followed Hippocrates in the distinction between healing by first and second intention, and, to promote healing by first intention, in desiring a clean and dry wound, with good apposition for exclusion of air. His tracts on the eye are lost; but, so far as we know, his surgery was adopted in the main from the Alexandrians, and from Soranus. However, Galen successfully resected the sternum for caries, exposing the heart; and he excised a splintered shoulder blade: moreover, with all his bent to speculative reason, we have no hint that he fell into the medieval abyss of regarding surgery as unfit for a scholar and a gentleman.

As a positive discipline the diseases of women may be counted with surgery; but within our limits that subject cannot be discussed separately. However it would never do to omit the name of no less a physician of the time—Soranus of Ephesus—who, by the accident of surviving records, is chiefly associated with these diseases. Soranus practised at Rome under Trajan and Hadrian, and

was therefore a contemporary of Archigenes, and little older than Galen. If in breadth of thought and swiftness of invention Soranus pales before Galen, yet in sober moments we may be tempted to regard him as the greater physician. In any case he must rank with Galen as one of the greatest physicians of antiquity. If the Methodists, of whom Soranus was the chief, fashioned for themselves the yoke of "strictum and laxum" as the poles of a new physiology, yet it is not easy to say that by this doctrine they were more entangled than were the dogmatists by the humoral doctrine, than was Hoffmann by "tone and atony," or the other systematists of the eighteenth century by their respective notions; physicians, many of them at any rate, masters in medicine nevertheless. The treatise of Soranus on Diseases of Women may be ranked with the surgical treatises of Hippocrates as a classic which no lapse of time can efface; and if on the degree of his influence as a general surgeon, and on those remnants of his surgical writings which have floated down to us on such rafts as Aetius and Paul of Egina, we have to assign to Soranus a place much lower than Hippocrates, yet his place was considerable enough to testify that in the Empire, as in Ionia and Alexandria, Medicine was saved by the honour and vitality of its surgery from the fictions and the petrifications of philosophical systems. If in many directions, as for instance in the treatment of empyema, Soranus evidently fell behind Hippocrates, on the detail of

operations for hernia, and even for stone, he was clearer than Celsus.

After Galen and Soranus Medicine came to the evening of its second day, to the long night before the rise of the Arabian, Italian, and French surgeons of the thirteenth and fourteenth centuries. By the divulsion of the Empire, by the degradation of morals to which even Pliny and Galen had begun to bear witness, and by the inroads of barbarians, arts and sciences were trampled under foot in the West until by the iron scaffold of the Faith a new society should be erected. In the East was more tranquillity; and the night was illumined by moons, such as Oribasius, Alexander of Tralles, and Paul of Egina, by whose reflected light men groped their way. To these physicians our debt is rather one of preservation of good tradition than of discovery. Alexander was no great surgeon; but he tells us of the diagnosis of ascites by percussion, of anasarca by pitting, of large spleen by palpation; and he makes some shrewd remarks on urinary sediments: still all these were parts no doubt of the current knowledge of his time. Such swallows made no summer; and their work lies out of my argument that surgery, though scorned by the high stomachs of the Middle Ages, has never been the child or the humble companion of medicine but the stone of the corner and the key to its true method.

Not only did Greek Medicine reach the medieval physicians in a fragmentary, mutilated and per-

verted form, but in this form Medicine came to them untempered. A mutilated and special tradition was separated from the organism of Greek accomplishment; it was deprived of the Greek breadth of thought, of the Greek spirit of intellectual freedom. Remnants of Greek lore, thus distorted never coherent, lay heavily upon minds unprepared to assimilate or use them. The mystical tendency of thought in the Middle Ages, the disposition to ontological absoluteness, the reliance upon precision of argument as the means of attaining truth, the transfusion of doctrine with Eastern fantasies, made of the Greek Medicine a widely different and far less scientific conception. By its ontological form medieval thought led to the idea of a wound as an entity having a substantial existence apart from or imposed upon the body; and, as such, possessed of its own modes and phases of life, modes and phases susceptible of independent fashion and direction under the hand of the physician. Moreover the scholastic tendency to dialectical subtleties led to an elaboration of factitious schedules and nomenclatures of these modes and phases, which enthralled the faculty of observation; while the mysticism manifested itself in magic, in egregious medicines and in barbarous perplexities of ingredients.

Thus it came about that in spite of the docile industry of certain physicians of the Byzantine period, medicine gradually sank not into sterility only but into deep degradation: for the wholesome discipline of practical surgery had fallen off. Eastern folk, who bear heaven-sent sores with fatal stoicism, repel

the profane hand of man;¹ and the tradition of Galen made for a plague of drugs which were least mischievous when merely superfluous. Nor was an overloaded and a filthy pharmacy the only sorrow of the sick; as art grew empty, sorcery, demonology and astrology entered more and more into the void. The Saracens, keen and intelligent as they were, and rich as were their gifts to the West, did little to remove and something perhaps to favour the aversion from surgery, and the social contempt of it, which culminated in the ban of the Council of Tours. Under the sanctions of Islam anatomy was impossible. By the door of the East, Rhazes, Albucasis, Avicenna—the Arabian Galen, had entered into a great scientific inheritance; and though they did not do much, it is true, to ennoble surgery, yet with them it was a grave and an honourable calling; with them Medicine had not yet lopped off her right arm. The Danaan gifts of the Western Church to Medicine issued in a far worse treachery. The Greek of Ireland, and of England in the time of Bede, was banished by Augustine and the Benedictine missionaries; and the medicine of Monte Cassino, itself indeed but a farrago of receipts, fell lower and lower in the monkish hostels of the West.² We have reason however to believe that

¹ In modern Islam I understand Medicine is now almost wholly in the hands of the barbers; the actual cautery is in much request; and cutting for stone, and operation for cataract are in the hands of specialists as they were from time immemorial in the West. Some of these customs are evident, even to the passing traveller, in Algeria, Tunisia, or Egypt.

² Before printing medical precepts were often put into verse, an aid to memory which it is not for us to scoff at; though when in

some fair surgery persisted, even in the cloister, until it was formally abandoned to the "secular arm" in A.D. 1163;¹ and books on surgery and midwifery began to disappear from conventual libraries. About the same time the University of Paris excluded all those who worked with their hands;² so that students of medicine had to abjure manual occupation, and to content themselves with syllogisms and inspections of urine, often without any inspection of the patient himself. From the University the Faculty of Medicine took its tone, and the surgical corporation of St. Côme aped the Faculty (p. 59). But by the expulsion of surgery from the liberal arts Medicine herself was eviscerated; the pernicious bisection of Medicine was made

the third century one Serenus Samonicus wrote *De medicina praecepta saluberrima*, in 1115 clumsy hexameters, we can scarcely wonder that Caracalla had him destroyed. Early in the twelfth century Odo de Meudon, or de Meune, wrote in poetry on 65 herbs and 12 medicines (Haeser); and the medical poetry of Gilles de Corbeuil, body physician of Philip Augustus, "De urinis" and "De pulsibus," and the versifications of Salerno are well known. (Cf. Kühn, *Abh. z. Gesch. d. Med.* Heft viii. 1904). Unfortunately even Fracastoro chose this fanciful shape for his work on Syphilis, and was hymned in English by Nahum Tate.

¹ The Rheims (A.D. 1125) and Lateran (A.D. 1139) Councils restricted the surgery of the clerical or, in other words, of the educated class, and no doubt feudal ideas did no less to abase its services; it was at Tours however that the sinister and perfidious "ecclesia abhorret a sanguine" was first pronounced.

² The denunciations of the Faculty of Medicine in Paris were almost as appalling as those of Ernulphus: e.g. "Famosum libellum mendacibus conviciis, impudentibus calumniis refertum," etc. etc. "Ipsam Torquetum indignum judicat, qui nequam medicinam faciat, propter temeritatem, impudentiam et verae medicinae ignorantiam . . . ipsum Torquetum similiaque hominum et opinionum portenta a se suisque finibus arceant," etc. etc. This specimen is of the late fifteenth century but is no unfair instance of the spirit of the University of Paris in the Middle Ages.

which has not yet spent its evil: the very foundation of the art was gone, and the clergy and the faculties, in France and England at any rate, devoted all their energies to shoring up the superstructure. Surgery had its revenge, its bitter revenge; but in the desecration of its own temple.

In the thirteenth and fourteenth centuries however surgery, hated and avoided by Medical Faculties, scorned in clerical and feudal circles, began in the hands of lowly and unlettered men to grow from the root; while inward medicine, withdrawing itself more and more from the sources and the laboratory of nature, hardened into the shell which till the seventeenth century bore but a false counterfeit of life. The surgeons of the thirteenth, fourteenth and fifteenth centuries, reared in base apprenticeships, not only illiterate but forbidden even the means of learning, lay under heavy disadvantages; yet by practical experience and technical resource they were making the future of our art. Towards the end of the fifteenth century indeed even this progress had slackened; it was soon reinforced however by new and urgent problems, not of the schools but of direct rough and tumble with nature: of these new problems, of which Paré became the chief interpreter, the wounds of firearms were perhaps the most urgent.

It is remarkable that around the papal chair the velvet of the hand of the Church was thicker than the iron. In the air of Rome or of Avignon the grim rigour of Paris was marvellously

softened. In Bologna, Padua and Montpellier Medicine could develop, if not freely, yet in tranquillity, and undivided. The peace of Constance (A.D. 1183) had enfranchised the great Italian cities, and a truce with the Empire gave to lay and clerical potentates time and occasion for the foundation of universities. In Italy the unity of Medicine, as in Greek and Latin ages, was still preserved: in Bologna there were indeed physicians and surgeons and barbers, but divisions had not yet gone deep; the titles melted into one another. In the twelfth century Gerard of Cremona, the translator of the Arabian versions of Greek Medicine, who by the frank and discreet selection of his authors did more for North Italy than Constantine had done in the eleventh for Monte Cassino and South Italy, rendered the surgical treatise of Albucasis (p. 44) into latin; and he left his books to the convent of St. Lucia, where he was buried: now in those days to a school books were a fortune.¹ With the rise of Bologna, and the richer endowments of its chairs, the school of Salerno, the oldest medical school of modern Europe, but the poorest in the books of the best Arab physicians, began to diminish; and Bologna, quickly surpassing the other Italian schools, now rivalled Montpellier and Paris. In Medicine indeed Italy² then led the world; in the great schools of Salerno, Naples, Bologna, Padua, there

¹ In the thirteenth century a learned Spanish Jew, Ferraguth, made the most important contributions from the Arabian schools.

² Italy had at this period a far wider and keener sense of unity than in later centuries.

was contained a strong lay and imperial tradition, which arrested hieratic ascendancy. Moreover latin medical prose, which was not established in France, England, or Germany till the middle of the thirteenth century,¹ was forming in Italy, even in the eleventh, upon the latin renderings of Arab versions of the Greek physicians; a condition of progress as vital for the time as the rise of the vernaculars in the fourteenth (p. 81).

Before the rise of Padua, Bologna was indeed a large and plenteous mother to Medicine in her full orb; yet even in Salerno far-seeing men had begun to dread the divorce of surgery from medicine. In the middle of the thirteenth century Bruno, a Calabrian probably educated at Salerno, in his "*Chirurgia Magna*," a work which, although a motley blend of Hippocrates, Galen, Paul of Egina and the Arabs, was that of a learned and experienced man, bitterly resents the separation of medicine from surgery by celibate clerks who in false squeamishness shirked operations.² Even

¹ This great service was of course first undertaken by Celsus, and performed consummately; though where latin fell short he had to insert "quod Graeci vocant" and the like. But, as the eminent physicians of the Empire after his time were Greeks, Celsus, to the grievous misfortune of Europe, was practically forgotten till Thomas of Sarzanne's (afterwards Nicholas V.) discovery of the Ambrosian manuscript (p. 55) in 1443. Nevertheless from some hints of Cassiodorus, which are possibly allusions to Celsus, and again of Gerbert (Sylvester II.) it would seem that even in the tenth century Celsus was read in some monastic libraries. On the other hand his treatise was printed as early as 1478 and sixty latin editions followed between that date and the time of Fabricius who declared:—"Admirabilis Celsus in omnibus, quem nocturna versare manu, versare diurno consulo." How Morgagni studied Celsus, and enriched his work with commentaries, is still better known. Aretæus was little known in the Middle Ages.

² Yet even in early Salernitan times there was a class of inferior

in Italy the clergy carried much weight in university graduation, and the students in all faculties bore the tonsure. And if Papal Bulls conferred privileges, they usually implied or imposed restrictions. When in some places a lower examination was provided for unclerky, that is in other words, illiterate, persons desiring to practise as surgeons only, the wedge was driven in deeper. The important Salernitan treatise—*The Glosses of the Four Masters on the Surgery of Roger and Roland*, edited by Daremberg and de Renzi, begins with regretting the decadence of surgery, which these masters attribute to two causes; namely, the division of surgery from medicine, and the neglect of anatomy. By the wisdom of Bologna and Naples, where were founded chairs of surgery, this ill-starred divorce was postponed; in his University of Naples indeed Frederick the Second made it a condition that surgery should be an essential part of Medicine, should occupy as long a course of study, and should be founded on anatomy “without which no operator can be successful.”

The School of Salerno was the first renascence of clinical experience; and Roger, the Salernitan, and Roland of Parma, upon whose surgery was founded the commentary of *The Four Masters*,¹

barbers or surgeons; for Bruno himself, while claiming the right of performing “all operations,” yet in respect of minor practice excuses himself thus: “*praeterquam de scarificatione et flebotomia, que licet cyrurgie species habeantur . . . noluerunt medici propter indecentiam exercere sed illas barberiorum in manibus reliquerunt.*” (Quoted by Julius Pagel in Puschmann’s *Handbuch*.)

¹ In Cambridge we have two MSS. of the *Four Masters*; that in the Peterhouse Library being the finer example. It is a folio

stand like Twin Brethren in the dawn of modern Medicine, bearing the very names of romance. Roger's "*Practica Chirurgiæ*" was written in 1180, and was re-edited by Roland nearly a hundred years later. It was no mere re-cooking of Albucasis: although of course it rests upon the traditional surgery of his day, there are not a few points of interest in the book, such as certain descriptions suggestive of syphilis. Under the title of the paragraph—for it is no more—*De cancro in virga virili*, carcinoma is included, but probably syphilis also. In some of these cases they tell us phagedena ensued. Before Theodoric, Roger refractured badly united bones. For hæmorrhage he used styptics, the suture, or the ligature; the ligature he learned no doubt from Paul: but Roger, like most or all qualified practitioners of the period, was a "wound-surgeon"; that is he did not undertake the larger operations. He warns against operating in cancer, especially if of

on vellum, written in a good fourteenth century hand, and evidently not a scholar's but a professor's copy. It is neatly illuminated and rubricated. The title is *Cirurgia iiii magistrorum cum additionibus Rolandi*. The volume contains in the first place the "Breviarium Constantini qui dicitur viaticus, cum glossulis Gerardi." This work extends to 143 ff., that of the Four Masters to about 80. One may see that Roger's tract on surgery owes much to Constantine's *Viaticum*. Who the four masters were who developed Roger's tract into a still more interesting work is mere speculation. Roland's additions were composed in 1264. The Peterhouse scribe entitles the work as of Mag. Rogerus and three others, and gives 1280 A.D. as the date of its appearance. This may have been the date of the early (original?) copy now in Florence (Libr. Magliabecchi). This I have not seen, but I understand that this copy Mag. Guido aretinus (Arensium) "correxit et manifestavit," and it is to the care of this editor that the Peterhouse text is attributed.

uterus or rectum. He was in favour, as a rule, of immediate extraction of weapons from their wounds; in these wounds, even after extrusion of the foreign body, he promoted coction or suppuration, and dressed them with galenical salves on lint. His bandaging seems to have been very efficient. To these points especially—to the withdrawal of the weapon, to the promotion of pus, and to unctuous dressings—I would call your attention; for now we are approaching more nearly the controversy which, pale reflexion as it may be of the great surgical regeneration of the nineteenth century, is, historically speaking, of singular interest. Less blessed than we, our fathers determined this controversy the wrong way, and thereby brought upon themselves, and upon their children for many generations, malpractices and tortures which—or so it seems to us—a contrary decision would have averted.

Let us now return to Bologna. Hugh of Lucca, says Malgaigne, is the first of the surgeons of modern Europe whom we can cite with honour. This tribute is a little strained; we may say, however, that of these honourable ancestors Hugh seems to have been the greatest. I say “seems to have been”; for Hugh is even a dimmer giant than Roger or Roland. We know that he served as surgeon in campaigns, and was present at the siege of Damietta; but of writing he left not a line. Such vision as we have of him we owe to his loyal disciple, perhaps his son, the Dominican Theodoric (Teodorico Borgognoni: A.D. 1205-1296),

Bishop of Cervia near Ravenna, confessor of Innocent IV.,¹ and the master of Henry of Mondeville. From Lucca Theodoric extended his practice far and wide, and, as Haeser remarks, made the noblest use of his earnings. He completed his treatise in 1266.² Salernitan practice needed the reforms of Theodoric "qui pulcherrimas cicatrices sine unguento aliquo inducebat." After some reference to Theodoric's work and a close study of Henry of Mondeville and Guy of Chauliac, I am of Haeser's opinion that Guy dealt with Theodoric unfairly; and, I would add, not only unfairly but even disastrously. What the later history of surgery might have been had that illustrious surgeon been more illustrious still, and carried forward the reform of Hugh, Theodoric, and Henry, is one of those historical speculations which may be left to the curious; the history of what has not happened cannot occupy much of the attention of serious students. It is sufficient to say that the judicious Guy held to galenism and to coction or suppuration, and rivetted upon surgery the grievous orthodoxy of which it had not purged itself even in the days of the studentship of many of us now living.³

What was Theodoric's message? He wrote:—

¹ I give the current story, but there is some evidence of two Theodorics—the Bishop, and a surgeon, by birth a Catalan.

² Dr. Payne (FitzPatrick Lectures for 1904) says that Theodoric took his description of leprosy from Gilbertus Anglicus, a description evidently at first hand, and in many respects very accurate.

³ Dr. Ernst Becker in his interesting tract on Medicine in medieval Hildesheim (Berlin, 1899) in estimating the value of medical fees in the fifteenth century says we must remember the long duration of attendances "bei der wohl regelmässig eintretenden Eiterung aller Wunden."

“for it is not necessary, as Roger and Roland have written, as many of their disciples teach, and as all modern surgeons profess, that pus should be generated in wounds. No error can be greater than this. Such a practice is indeed to hinder nature, to prolong the disease, and to prevent the conglutination and consolidation of the wound.” (Book II. c. 27.) In principle what more did Lister say than this? Henry of Mondeville made a hard fight for the new principle, but the advocates of suppuration won all along the line; and for centuries to come poultices and grease were still to be applied to fresh wounds; and tents, plastered with irritants to promote suppuration, were still to be thrust into the recesses of them, even when there was no foreign matter to be discharged. If after all this erysipelas set in—well, says Henry, we will lay it at the door of St. Eligius!

It is not easy to trace the growth of opinion on the process of healing by suppuration. The Hippocratic schools are responsible for the original form of the doctrine of the four humours and for the conception of crudity and coction; but in this school, and probably in Alexandria, if we may judge by Celsus, the practice of wound surgery was, as I have said (p. 8), sound on the whole. Speculation was not allowed to vitiate positive and direct experience. It must not be forgotten that suppuration was a rude method of expelling the foulness of wounds; but we must attribute the enormous vogue of treating wounds by salves and

sophistry, to the medieval travesty of Galen, and to that galenical machine which, in the manufacture of opinion, was as exacting and as inveterate as the aristotelian (p. 20). Wine was an old remedy in wounds; before Hippocrates it was exhibited by the Good Samaritan. Rhazes used alcohol as an antiseptic wound-wash; but he complicated his practice with a mystical polypharmacy. Hugh and Theodoric denounced the suppurative remedies and promoted healing by first intention. For the fresh wound they rejected oils and salves as too slippery for union, and poultices as too moist ("oleum et caetera unctuosa labefaciunt et maculant vulnus"): they washed the wound with wine only, scrupulously removing every foreign particle; then they brought the edges together, forbidding any of the wine or other dressing to remain within. As with the genuine Hippocratic school, a dry and adhesive edge was their desire. Nature, they said, produces the means of union in a viscous exudation, or balm—as Paracelsus called it, a word which Paré and Würtz adopted. In stale wounds they did their best to obtain union by cleansing, desiccation, and refreshing of the edges. Upon the outer surface they laid lint steeped in wine. Powders however they regarded as too desiccating, for powders thus shut in decomposing matters ("saniem incarcerant"); wine, after washing, purifying, and drying the raw surfaces, evaporates. The quick, shrewd, and rational observation and the original genius of Theodoric I would gladly illustrate did time permit; in passing I may say that he

was the first to notice salivation as the result of administration of mercury in "skin diseases."¹

Of the adherents of Hugh and Theodoric was the well-known Arnold of Villanova, the prototype of Basil Valentine and Paracelsus, and the champion of spirits of wine; a visionary indeed but a man of mark. He tells us naïvely that, like all the wound surgeons of his time, he flinched from large operations because of the "venae pulsatiles" which are so dangerous, defying even the cautery. Amputations of the larger limbs, I repeat, were rarely undertaken by any kind of surgeon; and the radical cure of hernia, cutting for stone, and eye operations were performed, often brutally enough, by travelling surgeons of the short robe, who were usually out of reach of the avenger before the result became manifest. Franco, as we shall presently see, was the first modern surgeon to raise these operations again to the standard of Celsus.

Both for his own great merits, as an original and independent observer, and as the master of Lanfranc, William Salicet (Guglielmo Salicetti of Piacenza, in latin use G. Placentinus or de Saliceto—now Cadeo) was eminent among the great Italian physicians of the latter half of the thirteenth century. Now these great Italians were as distinguished in surgery as in medicine, and William was

¹ Theodoric's treatise is to be found in most of the early printed collections of surgical treatises which were published in Venice: e.g. that of 1519. I ought perhaps to say this Address was written—and indeed delivered at St. Louis, before I had lighted on the article *Gesch. d. Medizin im Mittelalter* in the new volume of Puschmann's *Handbuch* by that admirable historian Dr. Pagel.

one of the protestants of the period against the division of surgery from inner medicine; a division which he regarded as a separation of Medicine from intimate touch with nature. Like Lanfranc and the other great surgeons of the Italian tradition, and unlike Franco and Paré, he had the advantage of the liberal university education of Italy; but, like Paré and Würtz, he had large practical experience in hospital and in the battlefield. He practised first at Bologna, afterwards in Verona. William fully recognised that surgery cannot be learned from books only. His *Surgery* contains many case histories, for he rightly opined that good notes of cases are the soundest foundation of good practice; and in this opinion and method Lanfranc followed him. William discovered that dropsy may be due to a "durities renum"; he substituted the knife for the arabist abuse of the cautery; he investigated the causes of the failure of healing by first intention; he described the danger of wounds of the neck; he sutured divided nerves; he forwarded the diagnosis of suppurative disease of the hip; and he referred chancre and phagedæna to "coitus cum meretrice."

Lanfranc (Lanfranchi), like William Salicet a clerkly physician, was driven from Milan by the violence of the Visconti; he fled to Lyons, and in 1295 to Paris, where he became a founder of French surgery, and gave a temporary renown to the surgical College of St. Côme, which had then received formal institution from St. Louis. He established clinical classes, and honourably and explicitly taught in

them all he knew. We learn from Mondeville, and many another source, that one cause of the poverty and defect of medieval medicine lay in the jealous secretiveness of its practitioners, a reticence which they carried even into their private consultations.¹ Seeing that even the greatest of them lifted matter literally and in bulk from others without the smallest sign of acknowledgment, this reticence is scarcely surprising. Theodoric himself had deferred to put his experience into writing till his old age, and much book-making was stopped by this jealousy; a result which the hearer will regard, as his mood may be, with thankfulness or with regret.

Lanfranc's "*Chirurgia Magna*" was a great work, written by a reverent but independent follower of Salicet. He distinguished between venous and arterial hæmorrhage, and used styptics (rabbit's fur, aloes, and white of egg was a popular styptic in elder surgery), digital compression for an hour, or in severe cases ligature. His chapter on injuries of the head is one of the classics of medieval surgery. Clerk as he was, Lanfranc nevertheless saw but the more clearly the danger of

¹ Even in the sixteenth century no less a man than Galileo declined to make public his secret method of grinding lenses till near his death. A veterinary surgeon, who flourished greatly in Yorkshire some hundred years ago as a marvellously successful operator, astutely evaded all prying and questioning into his secret, even when in imminent peril on a bed of sickness. He survived to carry all before him for many years longer. At length, bowed down by old age and decrepitude, he was again implored by his son to tell what he did in the secret half hour before operating. Life was ebbing at last, and the worn out old man whispered with his passing breath "I biles my tools."

separating surgery from medicine. "Good God!" he exclaims, "why this abandoning of operations by physicians to lay persons, disdaining surgery, as I perceive, because they do not know how to operate . . . an abuse which has reached such a point that the vulgar begin to think the same man cannot know medicine and surgery. . . . I say however that no man can be a good physician who has no knowledge of operative surgery; a knowledge of both branches is essential." (*Chir. Magna.*) Is it not strange that this ancient was wiser than most of us are even yet!

In the Medicine of the Netherlands one of the pupils of Lanfranc, a Flemish physician named Yperman, appears to have been the greatest name before Vesalius. In the recent edition of M. Broeckx, no doubt an excellent text, there is no translation of the Dutch; not even an analysis of the contents. Now it is not given to many of us to read Dutch; in the midst of other tasks one can but decipher this passage or that, in a literal way, without however gaining a sense of the general tone or qualities of the author. The father of Flemish surgery was born, probably at Ypres, at the close of the thirteenth century. He completed his studies in Paris, as a pupil of Lanfranc, with whom he kept up some friendship after his return to Ypres, where he settled in practice. He became entitled to be called "Master" in the year 1303-4. He was not in holy orders, but was a clerk, in the sense of academic culture and degree; his writings indeed

reveal a learned as well as a sagacious and skilful surgeon. In one passage he describes what a good surgeon ought to be, and among his requirements are grammar, rhetoric and ethics ; moreover, says M. Broeckx, a lofty tone animates all his work. He displays—the same critic tells us—a genius for surgery, and sturdily held his own, even with Lanfranc himself. Yperman describes the ligature, and, a few lines lower down, torsion of arteries. In two of the manuscripts, one of which I have examined in the library of St. John's College in Cambridge, are not a few drawings of instruments. The date of his death is unknown. This great surgeon, whose name won almost a proverbial renown, worked for good in the midst of a degraded surgery of salves and superstitions ; but his writings, strangely enough, were lost in oblivion for six centuries ! Copies of them in Flemish were discovered in the year 1818. It seems certain that he wrote the first manuscript in latin, for the use of his son ; and that later copies were written in Flemish, but we have no copy in his own handwriting. That in St. John's College is evidently a school copy, and may be compared with the much finer MS. of Lanfranc, a professor's copy, in the same library. Yperman wrote also a treatise, now very incomplete, on inner medicine, which also indicates, says Dr. Pagel,¹ considerable originality and self-reliance. In comparing these treatises, I am struck, in the *Medicine*, by the little reliance he placed on the physicians ; he does not quote

¹ Puschmann's *Handbuch*, vol. i. p. 737.

more than a dozen of them ; in the *Surgery* on the other hand he quotes from surgical authors many times on a page. May we not thus infer the opinion of an observer so independent and penetrating as Yperman on the comparative poverty of the medicine of the period ?

The early history of French surgery, to which after a brief digression I return, has been diminished by the light of Paré, which eclipsed the illustrious men who went before him and beside him ; of these indigenous French surgeons Henry of Mondeville and Guy of Chauliac were the chief. The *Chirurgia Magna* of Guy may be regarded indeed as the foundation of modern surgical doctrine in Western Europe. In Henry of Mondeville, of Montpellier and Paris, we still find the clerkly physician who notwithstanding vindicated for surgery its true place in Medicine. More clear-headed in this respect than Guy, who claimed for surgery only a place beside medicine and coequal with it, Henry rightly declared, with Galen, that surgery is but a method of treatment, and belongs to all Medicine. Haeser seems to me to do less than justice to this hardy and original reformer, the last champion in his day of two causes—the solidarity of Medicine, and union by first intention ; the second of these causes was lost for 600 years, the first is not fully won even yet. Of his student life little is known. It seems probable that he was educated at Montpellier, and certainly he was a pupil of Theodorice in Italy. Henry's writings, rich in mother

wit, and only too racy of worldly wisdom, are as entertaining as they are instructive. For their audacity of opinion and biting satire they were displeasing to the Church, and consequently remained long unprinted; thus their fame was obscured, and Guy of Chauliac got a quiet opportunity of appropriating no little of them. The Church, to extend a rigid frame for society as widely as possible, took under its protection the Civil as well as the Canon Law; and in Medicine its clerks found, in the galenist code, a congruous system of dogma. But with mordant raillery Henry declared that God did not exhaust His creative power in making Galen; he twitted the clerks who were supposed to know surgery by the grace of God, and asked how a man is to make even so small a thing as a nail by listening to lectures on the art, or indeed by merely watching others do it for ever so long. As himself a clerk, he reminds us of the well-known chapter in the *Ethics* where we are told to learn virtue by the practice of it; as builders learn by building, and harpers by playing the harp. With Lanfranc he insisted on anatomy as the foundation of Medicine; at Montpellier, where he had some relations with Gordon the learned author of the *Liberum Medicinæ*, he taught anatomy by bones and pictures, as he had learnt it at Bologna; and he prefixed an anatomical introduction to his *Surgery*, as Guy, Paré and others did after him. While declaring that too much faith in books chokes natural talent, he resented almost with violence the gibe that surgery is merely a handicraft; if the mind must inform the hand in its operation,

the hand in its turn instructs the mind to interpret the general proposition by the particular instance. By experience without reason, he says, we make some progress, but by reason without experience we cannot get along at all. He lashes the physicians and counsels the students of his time with the merciless wit of Petrarch, Rabelais or Molière, and with the worldly wisdom of Polonius. The poor man's case every doctor tries to shuffle out of; the high-born and rich, with their impatient changes of doctors and their deficiency of ideas, are sketched as vividly as if he had lived to-day: some of them he says also "*malentes in corporibus pati, quam in bursa.*" Yet after all his device to out-cunning the cunning, and to out-cozen the cozeners, he says well—"if you have operated conscientiously on the rich for a proper fee, and on the poor for charity, you need not play the monk, nor make pilgrimages for your soul."

Into Paris then, in academical form such as we have described it, Henry of Mondeville entered as, for the most part, a loyal disciple of Lanfranc; and aided, as it would seem, by John Pitard,¹ Surgeon to Philip the Fair, attempted for wounds to banish Galen's salve surgery, and to introduce the new methods of Hugh and Theodoric: for his pains he

¹ Jean Pitard or Pitart (Giovanni Pitardi), like Lanfranc, was probably one of the Italian academic surgical physicians who to the benefit of France were driven from Italy by wars and civil commotion. He was indeed one of those great physicians, like Hugh of Lucca, whose radiance has persisted to our own day, although no line of his writings, if ever he wrote any, survives. By the College of St. Côme he was raised to an almost mythical renown, as a reputed founder.

exposed himself to bad language, threats and perils ; and, "had it not been for Truth and Charles of Valois," to far worse things. So he warns the young and poor surgeon not to plough the sand ; but to prefer complaisance to truth, and ease to new ideas. I will summarise briefly the teaching of Mondeville on the cardinal features of the new method :—Wash the wound scrupulously from all foreign matter ; use no probes, no tents—except under special circumstances ; apply no oily or irritant matters ; *avoid the formation of pus, which is not a stage of healing but a complication.* "Wounds dry much better before suppuration than after it." "Sequitur ergo minor probata quod in omni vulnere in quantum possumus evitare causas generationis saniei. Sequitur ulterius conclusio principalis quod possibile est omne vulnus in quantum hujusmodi sic procuratum curari absque eo quod fiat in eo notabilis generatio saniei." Theodoric had said before him "Sanies vulnus corrodet et auget." Henry then proceeds to combat those galenist doctrines which were contrary to his own experience, and proceeds thus :—Distinguish always between oozing hæmorrhage, hæmorrhage by jets, and that which pumps out of an inward wound ; using styptics for oozing, and for jets the cautery or, where practicable, digital compression for not less than a full hour (*vide* p. 34). In another place he points out the fault of the cautery—that when the eschar falls the hæmorrhage may recur, and the wound must be disturbed for a second application. So for large vessels he advises acupuncture, in these words :—"Infigatur acus cum

filo sub utraque extremitate venae aut arteriae, et nectatur illud filum et fortiter stringatur." "But let the vessel be isolated from all surrounding parts with the knife, and torsion may be practised with ligature." His words are (Oportet) "scindere carnem exteriorem quae est supra extremitates venae aut arteriae e qua fluit sanguis, deinde dictas extremitates extrahere, torquere, et ligare." Lanfranc had given the warning not to let a nerve get caught in a ligature.¹ Henry proceeds—do not, as Galen teaches, allow the wound to bleed, with the notion of preventing inflammation; for you will only weaken the patient's vitality (virtus), give him two diseases instead of one, and favour secondary hæmorrhage. When your dressings have been carefully made, do not interfere with them for some days; keep the air out, for a wound left in contact with the air suppurates; however, should pain and heat arise, open and wash out again, or even a poultice may be necessary; but do not pull your dressings about, nature works better alone: if first intention fail she may succeed in the second, as a jeweller if he can solder gold to gold does so, if not, he has to take to borax; these resources however we learn well not by arguing but by operating.² By the

¹ I have read a story somewhere in medieval surgical literature of a patient whose musculo-spiral nerve was thus caught and crushed by a surgeon while tying an artery of the arm. Thenceforth the wretched operator hardly dare show himself in the streets, for the patient would furiously pursue him, shaking the palsied arm and hurling execrations.

² The reader must understand the conviction was rooted in the medieval mind that the way to discover truth was by disputation.

new method you will have no stinks, shorter convalescence, and clean thin scars. In wounds of the neck he says that alterations of the voice suggest some implication of the larynx. When using the word "Nature" he freely admits that the word is an equivocal one; but he would speak of her allegorically, as "a lute-player to whose melodies the physician has to dance." Here he detaches himself from medieval ontology (pp. 20 and 50) and returns to that ministry of nature which was the key to the Medicine of Hippocrates, and was renewed again in Paré's admirable "Je l'ai pansay, Dieu le guarit."

To illustrate the care of this surgeon I will quote also the following instructions:—"Always put your needles and thread in order before you begin to operate, and the thread not in a tangle, or you will have to wait and rethread it; now blood will not wait." He then describes an ingenious turn—not a knot—of the thread, so that by one twitch it will come straight away. Needles are to be of various sizes, triangular and sharp, and *clean, or they will infect the wound*; there must be grooves by the sides of the eye into which the thread may fall so as not to hurt as the flesh is pierced. The processes of suture, a prolific source of controversy and various practice in medieval surgery—as the fear of access of air (p. 9), or of retention of putrid matters had the ascendancy—are enjoined with no less precision and foresight. If the edges of a wound be altered by exposure they must be refreshed. "If treated on Theodoric's and my instructions, *every simple wound will heal*

without any notable quantity of pus." Every cause of formation of pus is to be avoided, not only irritating applications ("medicinae quae faciunt nasci pus," says Theodoric), but exposure, high diet, œdema, or local plethora. "Many more surgeons know how to cause suppuration than how to heal a wound."¹

His caustic and reckless wit is manifest in his remarks on the effects of the mind on the body. If your patient is losing heart tell him he has been nominated to a canonry: never mind whether your story be true or untrue.

For the misfortune of Europe social progress is discontinuous; the civil faction fights of Italy in the fourteenth century, the schism of the Papacy, and a wave of mysticism, drew much of the life from the universities of this gifted people, then and in the fifteenth century so apt to engraft the fruits of art upon the conceptions of learning. Petrarch lamented the flagging of Salerno, Bologna, and Padua. Boccaccio found the library of Monte Cassino doorless, the grass growing on the window-sills, and the books covered with filth. Bologna was drooping in spite of Mundino, the father of modern anatomy; but as it drooped so Montpellier waxed. In the thirteenth and fourteenth centuries, as I

¹ The copy of Henry of Mondeville I have chiefly used is in old French, published by the Society of Old French Texts, edited by Dr. A. Bos from the unique MS. of the Bibliothèque Nationale, Paris, in 1897. But Henry being a clerk, wrote, what was probably the original copy of his *Surgery*, in latin. This first text (from which I have quoted) was edited by Dr. Pagel in 1892. The edition of Nicaise (Paris, 1893) is of course indispensable.

have said (p. 24), books were to a university what the millionaire is, or ought to be, in the twentieth. Montpellier, with Italy on the East and Cordova on the West, became as rich in books as Paris was poor. Even in the later fourteenth century there appear to have been only nine medical works in the University of Paris; nor in the fifteenth was it much richer until in 1498 Charles VIII. carried off the library of St. Mark in Florence, which contained some 800 MSS., and Louis XII. that of Pavia; a transfer of books which probably led to Brissot's venesection revolt in 1514 (p. 107). But Montpellier had obtained all Constantine's and Gerard's translations; Charles of Anjou secured a copy of the *Continent* of Rhazes—till then unknown in Europe; and one of her elder sons—Arnold of Villanova (p. 32)—added to Gerard's translations of Avicenna. The *Surgery* of Albucasis, chiefly derived from the Sixth Book of Paul of Egina, and this in its turn from Celsus and Galen, was of great assistance in the early Middle Ages (p. 24), and handed on a body of surgery to Lanfranc, Salicet, Henry of Mondeville, and Guy of Chauliac. Much of Galen was at Montpellier; and, in the fourteenth century, the Sixth, or Surgical Book of Paul of Egina itself, afterwards to be lost again till the fifteenth. On the other hand Alexander of Tralles was no surgeon; and the surgery of Hippocrates was only apprehended in the allusions of Galen. The transcripts of Aetius were as yet undiscovered, and the original work of Celsus had been lost again.

Still Guy of Chauliac, who flourished in the second half of the fourteenth century, was enabled to feed his virile and inquisitive spirit on rich sources of learning. While he succeeded to the stores of Arnold and Gordon, with his just and cautious reason, and wealth of experience he cast out of them much of the sorcery, jugglery, astrology, and mysticism which were their reproach. Chauliac is a village in the Auvergne, and Guy was but a farmer's lad: it was by the aid of powerful friends that he studied at Toulouse and Montpellier, took orders, and the degree of Master of Medicine; in his time there was no degree of Doctor of Medicine in France. Then he studied anatomy at Bologna under Bertruccio, the successor of Mundino—a study which, with Henry, he regarded as the foundation of surgery. The surgeon ignorant of anatomy, he says, "carves the human body as a blind man carves wood." Thence he paid a brief visit to Paris where for a moment, by the renown of Lanfranc, Jean Pitard, and Henry of Mondeville, surgery was in the ascendant. For the moment the Church and the Faculty had not succeeded in paralysing the scientific arm of Medicine. Guy began practice in Lyons, whence he was called to Avignon by Clement VI. as "*venerabilis et circumspectus vir, dominus Guijo de Cauliaco, canonicus et praepositus ecclesiae Sancti Justi Lugduni, medicusque domini Nostri Pape.*" In Avignon he stayed, while other physicians fled, to minister to the victims of the plague (A.D. 1348), and he may have attended Laura, in spite of

Petrarch's tirades against all physicians, and even against Guy himself. His description of this epidemic is terrible in its naked simplicity. He did not indeed himself escape; he had an attack with bubo, and was ill for six weeks. He gave succour also in a later epidemic in Avignon, in 1360. His *Chirurgia Magna*, or *Inventarium seu Collectorium Artis chirurgicæ medicinalis*—so called in distinction to the meagre little handbooks or *Chirurgiæ Parvæ* compiled from the larger treatises—was in preparation in 1363. This great work I have studied carefully,¹ and not without prejudice; yet I cannot wonder that Fallopius compared the author to Hippocrates, or that John Freind calls him the Prince of Surgeons. It is rich, aphoristic, orderly and precise. As a clerk, he wrote in latin, in the awkward hybrid tongue that medical latin then was, containing many Arabian, Provençal and French words, but very little greek² (p. 25).

The sects of surgery in his time Guy made to be five:—(1) Those who (like Galen and himself) promoted coction and suppuration; (2) those who, after Theodoric, taught the dry management of wounds with washings of wine; (3) those who, after Lanfranc and Salicet, trimmed, and used mild unguents and plasters; (4) those who used charms, with oil, wool, and cabbage leaves, and supposed God to have deposited His grace “in verbis, herbis

¹ Chiefly in the edition of Nicaise, Paris, 1890; incidentally in various editions in the Library of Cambridge University.

² The curious reader may be referred to the three editions of *Guidon en francoys* by Jehan Falcon, Dean and Professor of Montpellier, published 1520, 1534, and 1537.

et lapidibus"; (5) women and silly folk, who sat and folded their hands under the will of God, Amen—which may remind us of one of the happy sayings of Henry that "the vulgar divide diseases into those which have causes and those which have none."

That Guy should have emancipated himself from the thralldom of authority is not to be expected; no man of his day could look upon Aristotle with an equal eye. Yet the critical spirit of the great southern surgeons was awake in him. He scorned the physicians of his day "who followed each other like cranes, whether for love or fear he would not say." In courtesy and honour he showed a far gentler and loftier temper than Henry; though indeed it is hard to say when Henry is serious, when ironical, and when medieval. In respect of its unity of reason and practice, Malgaigne considers Guy's *Surgery* a masterpiece of learned and luminous writing. Guy was a more adventurous surgeon than Lanfranc; as was indeed Franco, a later Provençal, than Paré. Guy still kept clear of cutting for stone, as Paré did after him; but Paré had the eminent example of Franco before his eyes. Guy did, however, operate for radical cure of hernia, and for cataract; operations till his time left wholly to the wayfaring specialists.

Nevertheless in respect of surgical principles, as I have foreshadowed, Guy was not infallible. Too sedulous a disciple of galenism, he was as a deaf adder to the new message of Hugh of Lucca, Theodoric and Henry; and not only was he deaf himself but, as the authoritative writer of the early

renaissance, he closed the ears of his brethren, even to the day of Lister. This is the more remarkable as in Guy we find an historical sense, the first criticism of medicine and medical authors on broad lines of judgment, since Celsus. If his judgments were not always true they were always weighty. Even Haller never penned a more discriminating judgment than this of Guy on Galen: "fuit enim maximus in scientia demonstrativa"; this on Albucasis also is notable: — "omnes praedecessorum suorum majorum doctrinas congregavit, quas tamen non elegit." I regret to say his opinion of Gaddesden's *Rosa Anglicana*—"una rosa fatua et sine odore suavitatis"—is not to our credit.¹ In respect of the thesis I am supporting to-day, he says, "et usque ad eum (Avicenna) omnes inveniuntur fuisse physici et chirurgici. Sed post, vel propter lassiviam vel occupationem curarum, nimium separata fuit chirurgia et demissa in manus mechanicorum." Guy was a man rather of sound judgment than of penetrating insight. Rich and comprehensive as were his talents, he was not a man of genius as we speak of genius in Lanfranc or William Salicet; nor had he the ardour or the audacity of Henry. At the close of his century he appears rather as an equable, sensible and critical than an inventive spirit. As in the medieval schools, he was disposed to balance his authorities—Avicenna, Haly, Albucasis, Lanfranc, Theodoric, Salicet, Henry, and so forth—by enumeration rather than by

¹ Dr. Payne says that Guy had in view John of Gaddesden, not Gilbert (v. et Freind (2nd ed.) ii. 274).

appreciation. Shrewd, and full of learning and experience, he lacked the fine temerity of the greatest surgeons; with all his sagacity he was prone to be too judicious, too eclectic. For instance, Yperman the great fourteenth century surgeon of the Netherlands (p. 35), divided scrofulous patients into those who are touched by the king for the evil and those who are not; slyly adding that some get well without the touch, others are touched and do not get well; Guy on the other hand says sedately:—“*Concedo tamen quod virtute divina Serenissimus Rex Franciæ tangendo liberet multos.*” Moreover his influence, so long dominant, was, as I have said, exercised against the true principles of the treatment of wounds.

Unfortunately also, we find reflections upon surgeons of his own period which are harsh, unjust, and either ill informed or disingenuous. On the sense of literary honesty and magnanimity in those times we can only hold our peace. These virtues were unbegotten. Guy was a sinner; but even Paré sinned with him.

Of his substantial advances in surgery no sufficient account is possible; but some chief points, with the aid of Haeser, Malgaigne and Nicaise, I may briefly sum up thus:—He pointed out the dangers of surgery of the neck, among them that of injuring the voice by section of the recurrent laryngeal nerve, a precaution he probably learned from Paul. He urges a low diet for the wounded, as did Mondeville and many others. He uses sutures well and discreetly (p. 9), but with far too many

salves. On fractures of the skull he is at his best; he notes the escape of cerebro-spinal fluid, and the effect of pressure on the respiration. It is somewhat strange that, in days of war, the study of chest wounds had been rather neglected by Galen, Haly, and Avicenna; their practice however was to leave them open, lest pus should gather about the heart. Theodoric and Henry ordered chest wounds to be closed "lest the vital spirits escape." Guy also closed these wounds, unless there were any effusion to be removed. In empyema he objects to caustics, and prefers the knife. For hæmorrhages he used sutures—a little too closely perhaps, styptics, cautery, or ligature. Sinuses he dilated with tents of gentian root, or he incised them upon a director. On ulcers his large experience is fully manifest; he describes the carcinomatous kind as hopeless, unless the mass can be excised at a very early stage and the incision followed by caustics. If in fractures and dislocations he tells us nothing new, these sections testify to a remarkable fulness of knowledge at a period when the Hippocratic treatises were unknown. Haeser says that in respect of position in fractured femur he was the best physician of the Middle Ages. On the other hand my own reading tells me that Guy restored and reanimated the vicious doctrine that the healing of a wound is the work of the surgeon; that not by natural process and bodily function is it brought about—as Theodoric and Henry had taught—but by the educative means of the surgeon operating upon a modifiable entity (p. 20). In it, it is the surgeon who models,

who incarnates, who builds; who commands the elaborate methods and the recondite means—tents, tampons, salves and plasters—by which these processes are initiated and governed; who assembles the functions, engenders and regulates the new flesh, and knits up the scar.

With Guy of Chauliac, the ablest surgeon of his time, medieval medicine may be said to end. The vigorous push of surgery in the thirteenth and fourteenth centuries was checked in the West by the feudal pride and academic bigotry which, culminating in the reactionary ferocity of the Church, thrust surgery down into the ranks of illiterate barbers, reckless specialists, and adventurous charlatans. In Italy, however, the genius and bent of the people, for art as well as for philosophy, and the ascendancy of the secular element in the Universities, still kept surgery more nearly to its place as the positive and fruitful side of Medicine, and as "the scientific arm of the physician."¹ Provence, strengthened for a time by the Arabs on the south-west, by the Italians on the south-east, and by the Papal Court at Avignon, had produced Mondeville and Guy of Chauliac; and was to produce Franco. But the slackness of the Italian schools of medicine was temporary, as the advantages of Montpellier were temporary. In the fifteenth century Bologna rose again quickly to surpass all other schools, to surpass in vitality if not in

¹ An excellent phrase which I owe to Sir John Burdon Sanderson.

numbers Montpellier and even Paris. We have seen that before the rich endowments of its chairs Salerno, the oldest medical school of modern Europe, had diminished. Moreover, as Paris waxed, Montpellier and Toulouse, Oxford and Cambridge, stiffened under its harsh and sapless domination. In spite of the Italians and Mondeville, Guy's influence turned the tide back towards arabist and galenical polypharmacy and salve surgery; and turned it, not in France only but even in Italy itself, where he influenced Argelata, and in Germany, where he influenced Brunschwig (p. 91). During the fifteenth and sixteenth centuries, fifty-two editions of Guy's *Surgery* were printed; and it held the field until tradition was broken again in Italy by Fabricius, who founded surgery anew upon anatomy and upon the original texts of Hippocrates, Galen, Celsus and Paul, and fortified the new edifice with the work of his own talents and experience and those of his contemporaries, such as Fallopius and Eustachius. Still in Italy of the fifteenth century surgery never withered as it did in the West; if it slumbered for a spell, it soon awoke again, to be refreshed in the new hellenism.

Peter of Argelata (d. 1423), Doctor of Arts and Medicine, and a professor of Bologna, wrote an excellent *Surgery* full of personal observation; and, perhaps for the first time, was frank about his own mistakes. In some bolder adventure in operative work, as distinguished from mere wound-surgery, Peter followed the lead of Henry and Guy; and was himself a learned and skilful practitioner. He was

for a dry wound; but to this end used powders which, as we have seen, Hugh and Theodoric refused, as retentive of putrescent matters. He helped himself freely of course to Guy's writings, but was bold in preferring experience to authority. He used sutures for the larger wounds, with drainage tubes of perforated metal. He trepanned the long bones as well as the skull, and even operated in the lines of the specialists on hernia and stone. He cured fistula by incision, and in extraction of the dead foetus followed Guy's method of operating through a large spectrum.

Of one of Peter's pupils, Marcello Cumano, a surgeon known to few of us even by name, I must speak in passing; for, if De Renzi be correct, he was the first to write upon the wounds of firearms. Cumano was an army surgeon who died in the Morea, and the manuscript of his *Vade Mecum* lay unknown in Florence till 1650. It was printed not "eighteen" years later, but seventeen. I cannot discover the grounds of Haeser's commendation of this surgeon. The edition¹ which I had before me as I wrote this paragraph is but a "Chirurgia parva," a meagre collection of galenical receipts, many of them, it is important to note, for venereal eruptions; I discover not a gleam in it of surgical or medical sagacity. His writing on shot wounds is exiguous, even as a beginning. This paragraph is entitled *Dolor vulneris sclopeto illati vel ballista*. The pain is to be soothed by the warm application

¹ A collection of medical tracts published at Ulm. Ed. Velschius, 1667.

of oil of roses, of galbanum and of assafoetida. This receipt does not suggest that the opinion was then current that these wounds were poisoned; but the author does not discuss the matter, as Haeser seems to imply. The discovery of firearms shook not the nations only, but also the dominion of authority in Medicine, by raising, as we shall presently see, another and a new controversy on the treatment of wounds.

Leonardo Bertapaglia, another great Paduan Professor, flourished a little after Peter of Argelata, but was a man of far less originality. He held more closely to the Arabs, especially to Avicenna and salve surgery; he knew but little anatomy, and not only, like other wound surgeons, avoided major operations, but left even minor operations to the barbers, wherein he betrayed the weakness which had crept even into the surgery of the Universities of harassed Italy. Moreover we note in his *Surgery* the advancing influence of Arabian astrology in this century. Still, Bertapaglia did good service in investigating the conditions and improving the method of the ligature. His method was to draw the vessel forwards with a steel hook, to isolate it, to tie it with a flaxen thread, then, to prevent slipping, to pierce it with the needle and thread and, twisting the thread round, to make fast by knots. It was a clumsy method, but in isolation of the vessel was better than Paré's *ligature en masse*. He resected ribs in empyema, as Guy had done; he sutured wounds of the intestine, with the glover's ("furrier's") stitch, and used

softened catgut in preference to thread for the purpose.

At Padua, in the fifteenth century, by the hand of Montagnana the elder, were instituted the *Consilia*, or published collections of notes and reflections on cases, which played so efficient a part in the advance of clinical Medicine in the two following centuries. For Montagnana we cannot claim more than a commencement, yet he also was among the first of those who returned to the fountains of Greek. He quotes directly from Paul, whose writings had disappeared for a while after Guy used them; and from Celsus, whose great work had been recovered again, in 1443, in the church of St. Ambrose at Milan (p. 25 n.).

In the midst of these mainly arabist professors of Medicine of the fifteenth century arose Antonio Benivieni, to be revered as the forerunner of Morgagni, and as one of the greatest physicians of the late Middle Ages. This distinguished man, a Doctor of Medicine and a man of culture, was born in 1448 and died in 1502. He was not a professor but an eminent practitioner in Florence, at a period when, in spite of its platonism (p. 63), Florence on the whole was doing the most for science; for as Bologna turned to law Padua turned to humanism and philosophy. He was one of those fresh and independent observers who, like Mondeville, was oppressed by the authority neither of Arab nor Greek. Malgaigne claims for him the first performance of lithotrity; but even if this statement were correct,¹ Benivieni's case

¹ Lithotrity, or lithothripsy, is an old story. Attempts at it were made by Byzantines and Arabs, more or less as secrets of the

was in a woman, in whom the stone was hooked forward, and then knocked to bits with a punch.¹ Carefully as the bits were washed out, this operation in woman, even if it had not been anticipated, was no great matter in lithotripsy. Nor do his claims to our admiration rest upon his puncture of the hymen for retained menses; nor upon his division and slow extension of the cicatricial contractions of a burned arm, ingenious as these devices were. Nor again shall we admire Benivieni chiefly because he was the first to communicate his own matter tersely and practically, without fabricating a complete treatise to contain it, and without tricking it out with dogmatisings, ratiocination, or the chimeras of oriental lore. This is true enough, no doubt; but Malgaigne does not state that

adept. A remarkable passage from the *Corpus script. hist. Byzant.* (vol. ii. p. xxxiv.) is quoted by Haeser (Bk. i. p. 509) (I paraphrase the Greek, but keep closely to the meaning):—*In one afflicted with a very chronic dysuria instruments were passed by the natural passage (τοῦ φυσικοῦ ὑποβίου) into the bladder, which breaking up [the stones] (διαθρόνοντα) promoted their discharge and thus gave free issue to the urine.* Haller points out that a later surgeon, Sanctorius (*Comm. Avicennae*, 1626), pictured a trifid catheter with a spear in it, wherewith to pierce the stone, but regards it as a mere suggestion. In a MS. at Vercelli however Haeser says a long pair of nippers is figured with such a boring stem, the instrument to be passed *per urethram*. Ciucci of Arezzo and Rome (about 1650) invented such an instrument—very like that of Civiale; and says by its means his own bladder was relieved of a stone in three sittings. He adds that the bladder may be caught in the nippers and torn, when (the operator) “*misero patienti et lapidem et animam educit!*” In his own case he laid upon the operator “*ut mihi religiosissime obtemperasset,*” and that if he felt the least catch on the bladder the operator should stop instantly.

¹ Celsus tells us that the Alexandrine surgeon Ammonius (ὁ λιθότρομος) used the same means, in both sexes, to break up stones too large to pass by the perineal incision. (*Lib. vii. ch. 26, § 3.* Védère's Ed. p. 540.)

the little book *De abditis causis morborum* (brief title) was not published in any form by Antony Benivieni himself, but posthumously by his brother Jerome, who found these precious notes in Antony's desk after his death, and with the cordial consent of a friend,¹ competent in the subject, published them in 1506,² in the form which no doubt justly merits our admiration. Benivieni's chief fame for us is far more than all this; it is that he was the founder of pathological anatomy. So far as I know he was the first to make the custom and to declare the need of necropsy to reveal what he called not exactly "the secret causes" but the hidden causes of diseases. Before Vesalius, before Eustachius, he opened the bodies of the dead as deliberately and clear-sightedly as any pathologist in the spacious times of Baillie, Bright, and Addison. Virchow, in his address at Rome, said Morgagni was the first pathologist who, instead of asking What is disease? asked Where is it? But Benivieni asked this question plainly before Morgagni: not only, says he, must we observe the disease but also with more diligence search out the seat of it. The precept is so important I will quote the original words:—
"Oportet igitur medicum non solum morbum cognoscere, sed et locum in quo fit, diligentius perscrutari."
 Among his pathological reports are morbus coxae (two cases); biliary calculus (two cases); abscess of

¹ Rosalius, who says that the loss of such notes "magnum detrimentum, magna injuria fieret cum presentis tum futuri saeculi hominibus."

² The R.C.P.L. copy—a pretty one, containing *Scribonius Largus* also, was printed by Cratander of Basil in 1529.

the mesentery; thrombosis of the mesenteric vessels; stenosis of the intestine; some remarkable cardiac cases, several of "polypus" (clot, which was a will-of-the-wisp to the elder pathologists); scirrhus of the pylorus, and probably another case in the colon; ruptured bowel (two cases); caries of ribs with exposure of the heart (*vide* Galen's case, p. 17). He gives a good description of senile gangrene which even Paré did not discriminate. He seems to have had remarkable success in obtaining necropsies: concerning one fatal case he says plaintively "Sed nescio qua superstitione versi negantibus cognatis," etc. Of another he says "cadavere publicae utilitatis gratia inciso" (the case of cancer of the stomach).¹ With this admirable and original leader Italian Medicine of the fifteenth century closes gloriously, to slumber for some fifty years, till the dayspring of the new learning. Of his work Malgaigne says, and apparently with truth, that "up to now it is the only work on pathology which owes nothing to any one."²

Some of my readers may wonder how it is that

¹ It is interesting to note that Benivieni held the opinion of the march of the "French Pox," that it was from Spain to Italy, and from Italy to France. The pestilence seems to have received this name on the invasion of Naples by the French in 1495. The note on Benivieni as a pathologist in Signor Chiari's "History of Pathological Anatomy" in the second volume of Puschmann's *Handbuch*, seems to me very inadequate to the proper appreciation of his merits.

² Dodoens published an edition of Benivieni at Leyden in 1585, with notes of his own, which has not fallen in my way. Nor have I seen the fifty additional records discovered in the last century, and published by Puccinotti (see Haeser *in loc.*). Haeser tells us that we have to lament the loss of a work of Benivieni on Surgery. He says that for hæmorrhage he used the cautery "*incisam arteriam candente ferro inuro.*"

in discoursing of mediæval surgery I have not dwelt upon the surgical College of St. Côme of Paris. Well, St. Côme did no great things for surgery. The truth is that, infected with the exclusiveness and dialectical conceits of all the schools of Paris, St. Côme was almost ready to sacrifice surgery itself if thereby it might choke off its parasites the barbers. Lest they should be suspected of mixing their philosophy with facts, its members went about with their hands ostentatiously tied behind them. If perhaps Malgaigne speaks too contemptuously of St. Côme, it must be admitted that the College was in a false position throughout. In aping the Faculty of Medicine, it lost touch of mother earth without gaining any harbourage in the deep waters of the proud. Nay, such is the Nemesis of pride, the barbers came to command the position. It did not suit the Faculty to see the barbers weakened; for in their weakness lay the strength of the surgeons of St. Côme, who sought incessantly to appear as lettered clerks, to attach their College to the University, and even to claim a place beside the Faculty itself. To bring St. Côme to its knees, and to check the presumptuous claims of this Corporation on the privileges of the Faculty of Medicine, on a liberal education in arts and medicine, on a place in the university, on the suppression of unqualified surgical practice, and, less honourably, on relief from handicraft and urgent calls,¹ the Faculty had but to coquette with

¹ To be subject to urgent calls was in the opinion of the time the status of a slave. I trust that none of my readers can see any excuse for such a sentiment.

the barbers. Medicine, proclaimed the Faculty when it suited its purpose, contains the theoretical and the practical sides of surgery; a surgeon is therefore but the servant of the physician. If St. Côme sought to provide lectures in surgery, the Faculty, which kept possession of teaching licenses and desired in the surgeon a docile assistant, took the teaching from the college, and invited the barbers to lectures of its own. In their duplicity and conceit of caste physicians of the Faculty condescended even to publish books on surgery, books as arid and as insincere as their lectures. On the other hand, in the person of the King's Barber, the barbers had a secret and potent influence at Court.¹ The Faculty persisted in denying to St. Côme all "esoteric" teaching, all diagnosis, and all use of medical therapeutics. Aristotle was pronounced to be unfavourable to the "vulgarising of science." Joubert was attacked for editing Guy, but replied with dignity (in the notes to his edition). While the Faculty thus tried to prevent the access to letters of a presumptuous body of artisans, St. Côme in mimic arrogance disdained the barbers, sought to deny them the name of surgeon, and was jealous of the diffusion of technical knowledge among them in the vernacular tongue.² Thus, as it was only during the

¹ In 1372 the Barbers obtained the right "de curir et de guérir toutes manières de clous, bosses, apostumes, et plaies ouvertes en cas de péril, et autrement si les plaies n'étaient mortelles, sans pouvoir en estre empêchés par les mires, ou chirurgiens jurés." At Hildesheim at any rate the Barbers dedicated their guild (1487) to St. Côme and Damian (Becker, *loc. cit.* p. 29, n. 3).

² Tolet in his translation of Paul of Egina into latin (Lyons,

brief ascendancy of the great southern surgeons, such as Lanfranc, Pitard, and Henry of Mondeville, who were both surgeons and scholars, that St. Côme exercised any real and beneficial influence, I have not occupied myself with this College at any greater length.

In discussing French surgery of the fifteenth century we must distinguish then between the surgery of Paris, of the provinces, and of the rural districts. And it would be unjust to forget that in the latter half of the fifteenth century Paris suffered some reforms, although the public was then as convinced that orders were essential in a physician as now in a schoolmaster; celibacy was abolished for physicians, and with it diminished the allurements of prebends and rectories, and the pernicious practice of the "médecins reclus" (Buchärzte) who did not visit patients, nor even see them, but received their ambassadors, who brought gifts and vessels of urine, and carried back answers far more presumptuous than the wise response of Falstaff's physician.¹ Nevertheless reform in Paris was not only very grudging, but was capriciously favoured or thwarted by the Court. Fortunately however the surgeons were carried out of Paris into war, a far better school than the barren Faculty of Medicine.

1540) says he was not disposed to let the surgeons learn latin, as this would be to rival the physicians in knowledge "ce que les médecins ne doivent vouloir."

¹ In the many handbooks of the water casters to be found in our libraries are schedules of the colours and other superficial appearances of the urine with the proper medicines in a parallel column.

Montpellier towards the end of the fifteenth and in the sixteenth century fell upon evil days. Deserted by the Popes who had maintained the liberal traditions of Italy, ravaged by war, and her libraries rifled, it was a sign as well as a cause of farther decay that, to herself untrue, she fell under the influence of Paris, and committed the fatal error of separating surgery farther from medicine, whereby she cut Medicine away from its living root, forbade her graduates even to meddle with the craft, and abolished surgical teaching.

Meanwhile, however, the return of the Popes to Rome, and the displacement of Albucasis and Avicenna by the greek texts, renewed the shrivelling body of Medicine, and with the help of anatomy Italian Medicine awoke again; though until the days of Vesalius and Harvey the renaissance came rather of men of letters than of medicine. The Arabs and Paris said;—Why dissect if you trust Galen? But the Italian physicians insisted on verification; and therefore back to Italy again the earnest and clear-sighted students flocked from all regions. Vesalius was a young man when he professed in Padua, yet, young or venerable, where but in Italy would he have won, I will not say renown but even sufferance! If normal anatomy was not directly a reformer of Medicine, by way of anatomy came morbid anatomy, as conceived by the genius of Benivieni, of Morgagni, and of Valsalva; the galenical or humoral doctrine of pathology was sapped, and soaring in excelsis for the essence of disease gave place to grubbing for its roots.

We cannot make however brief an adventure on the history of Medicine in the sixteenth century, that dramatic century as vast and swift in the compass of its art and thought as bigoted and fierce in its reactions, without a livelier sense of that intimate dependence of Medicine upon the spirit of its age which we have recognised already. Tormented by pestilence and war, seeking a false succour in the black arts of the East, in astrology, magic, and priestcraft, our fathers of the sixteenth century fought a dark and troublous way to light, truth, and beauty. Amid materialism, indifference, and bold unbelief in Church and State, when even priests were making a mock of religion, it was the men of science, in the armour of natural knowledge, who awakened religion anew, and brought refreshment to stunted souls and withered hearts.¹ The platonism of this century, soon as it settled down on its lees, was for a while the powerful adversary of aristotelian orthodoxy, in cloister, in academy, and even in the Papal Chair. Da Vinci, Michael Angelo, Raphael, were Platonists; though, like Telesio who turned from the Church to natural philosophy, they rejected much of its flummery. Before them Petrarch had denounced inordinately, but he had given no lead. Vives, the Spanish Professor of Oxford and friend of Erasmus, was the first of a great procession of builders—De la Ramée, Palissy, Bacon, Charron, Gassendi, Descartes—who doomed the fabric of the dogmatic schools, and in letters and natural philosophy laid the stronger foundation of inductive

¹ For this true and profound reflection I am indebted to Haeser.

research. Vives urged the study of anatomy, and with De La Ramée (both of them laymen) declared the futility of lectures on Medicine without clinical instruction. Such instruction was established in Padua—by Montanus, and probably in Montpellier. Paracelsus, as ardent a system-maker as Galen, intoxicated by platonism and blinded by an impatient temper, did much service nevertheless in blowing his horn over against the ancient and toppling walls of convention; and, although he ignored anatomy, he sketched in some chemical background for Medicine. The great princes of Florence, Milan, Ferrara, and Mantua endowed liberal learning. More than a century before Battista Porta in Naples, and two centuries before Boyle and Wren in Oxford, Bessarion in Rome, Pomponius Laetus in Naples, Nicholas of Cusa in Germany had promoted associations of learned men which, directly and indirectly, were the strength of science in successive generations. In the sixteenth century Palissy founded the science of geology, a foundation scarcely built upon till the nineteenth. Bacon contrasted the “anticipatio,” or speculative conception of nature—which he calls a rash and precocious method—with the interpretation of nature; the logic of thought being perfect enough he proclaimed that the stuff and premises of it must be verified, and that experiment must not be desultory, but systematic and consistent (“seriatim et continenter”). Strangely lacking in the qualities of an investigator, and too violent in reaction against hypothesis, yet as a philosopher he inscribed on a monumental

page principles which Copernicus, Kepler, Galileo, Harvey, were putting into practice. Vesalius regenerated anatomy, by proving that Galen's anatomy was largely based upon dissection of apes and dogs, and in any case was faulty and defective.¹ In physiology Colombo and Cesalpini were preparing for Harvey. But ratiocination founded on scholastic dogmas is not upset in a year, nor in a century of years. A ruthless war against enlightenment lasted all the second moiety of the sixteenth century, and well on into the seventeenth; for, as Hippocrates warned us, experience is difficult, verification fallible, observation long and costly, occasion fleeting. Many changes however conspired to disturb the serenity of medical self-satisfaction, and to undermine the long domination of traditional medical doctrine which, even if genuine, would as a formal and transcendent authority have become sterile enough, and, as a bogus doctrine of partial and distorted texts, was infinitely mischievous. Now however "uralte Wasser steigen verjüngst." On the discovery of the original greek texts, the false texts, glosses and commentaries were put to shame; while the invention of hempen or rag papers in place of silk paper or parchment, the discovery of printing, and the vindication of the vernacular tongues sapped the privileges of the clerks.

I have said elsewhere,² that the aid of the

¹ The *De corporis humani fabrica Libri septem* appeared in the same year (1543) as the *De revolutionibus orbium celestium*.

² *Harveian Oration*, 1900.

humanists in the development of Medicine was no unmixed advantage; for if in art and letters they were reformers they were for the most part as scornful of handiwork, and as alien from natural knowledge, as the clerks and the nobles. It is true nevertheless that such men as Vidus Vidius—Francis the First's Regius Professor at the College of France—if themselves no very original observers, by leading their pupils back to the ancient texts, indirectly loosened the rusty chains of the galeno-arabist bondage, and of all such bondage; and in this work Vidius had successors greater than himself—such scientific humanists as Beroaldo of Bologna, Leoniceno of Ferrara, Linacre, Caius, and the two editors of the Hippocratic Canon, Cornarus and Foesius. From Petrarch to Molière great laymen had demanded why, if medicine were not a going concern, but a static doctrinal scheme derived, like the Athanasian Confession, from the fathers, and immutable, it needed any augurs, adepts, or illuminati for its comprehension and use. To this question there was no good answer; and thoughtful physicians influenced, perhaps insensibly, by the searching spirit of the greek texts of Hippocrates, began to stir in their sleep, and uneasily to suspect there were many maladies on which even this great ancient threw but a glimmering light or none,—such, for example, as syphilis and the great pestilences of the West, upon which new problems books began to appear, such as those of Fracastoro, Caius, and Baillou. Dialectical and scholastic as it was, Baillou's treatise made its mark

as the first comprehensive treatise on Epidemics since Hippocrates; in spite of himself he was compelled to teach what Galen did not know, to begin to discriminate certain fevers hitherto confounded under one name, and thus to develop symptomatology, and slowly and insensibly to bring into view authorities concurrent with the ancients themselves.

Other direct causes of the break-up of the frost were the use of firearms,¹ which made wounds that even Galen had failed to foresee or to provide against; a like defect of galenical doctrine in respect of syphilis and other epidemics; not defect only but grievous error in anatomy; the reform of this science; the germination of pathological anatomy; the prodigious discovery of a vast continent of which the omniscient ancients had no suspicion; a strange schism on venesection—whether, that is, it were orthodox to bleed on the side of the disease or on the opposite side (p. 107); and the revelation in the light of the genuine Hippocratic treatises of the incompetence of the Arabs in fractures and luxations.²

In the opening of the century Italian Medicine was still in the van until the birth of the great French surgeons, Franco and Paré; and of Gersdorff

¹ Although for siege work pieces of ordnance were used in the middle of the fourteenth century, field pieces and the small firearms did not come into use till a hundred years later. The first picture of a cannon is in an illuminated MS. of the fourteenth century in the Christchurch Library.

² The chief Greek texts were not directly accessible till towards the middle and end of the sixteenth century; but Aetius was discovered, and Celsus and Paul, more than once lost, were found again (pp. 25, note, and 55).

and Würtz in Germany. Among the great Italians of this time, first perhaps in interest was the unlucky Berengario da Carpi, a pioneer in anatomy—he tells us he had “dissected” a hundred bodies¹—and a Doctor of Medicine of Bologna, whose name has been made familiar to us by Cellini. Cellini maliciously twits Berengario on the enormous profits of his practice in the French pox; this he treated by mercurial inunctions. Cardinal Colonna, well known to us by his portrait by Raphael in the Uffizi, was one of his most lucrative patients. Berengar practised in Rome in the first part of the sixteenth century. Twice he extirpated the uterus for prolapsus; he wrote an able treatise on gunshot wounds; and in the course of his anatomical investigations he added a few facts to pathology. A still more celebrated physician was John of Vigo (1460-1520) who, as attached to that fighting Pope Julius II., saw much of field surgery. His *Surgery*, printed at Rome 1514, had enormous vogue, a vogue perhaps unique. If of Guy’s *Surgery*, at the end of the fifteenth century and the beginning of the sixteenth, there were, as we have seen, 52 editions, the run of editions and translations of Vigo seems to have been endless.

¹ It is not easy to know what in those days “dissection of a body” meant. The corpses soon became putrid, and on many occasions probably a public demonstration of the chief viscera sufficed. Moreover some of the bodies were probably of monkeys, or only of the domestic pig, so useful to medieval anatomists. That Berengar was an ardent anatomist however, even of the human subject, may be confirmed from the persecutions he suffered at the hands of the priests. Nevertheless all the anatomists before Vesalius professed to work only in the illustration and elaboration of Galen.

For since the work of Guy no standard surgical treatise had appeared. A French translation of Vigo's treatise on the wounds of firearms fell into the hands of Paré, and probably, as a modern and independent work, had, with Guy's *Surgery*, then the standard authority, an inspiring influence upon the barber's boy while he was shaving, trimming wigs, or brushing out the shop at cock-crow. Nevertheless the value of Vigo's work is far less; he may be called the last of the elder or didactic surgeons, he had little of the initiative of Fabricius, and drew freely on Guy. Yet he was a shrewd and skilful as well as a learned physician, who had read his Celsus to some profit. In his *Practica*, published at Rome in 1514, he observed that gangrene is apt to arise from bad bandaging in fractures, and from access of frost; also he compared wound gangrene with the dry senile form which, as I have said, had been described by Benivieni (p. 58); he noted fracture of the inner table of the skull without that of the outer; and he undertook certain of the graver operations, though not such as fell within the custom of the professional cutters—not, that is to say, hernia, stone, plastic work, or cataract: these he discreetly left to the "vagabonds qui courent de pais en pais." He treated syphilis with mercurial inunctions. In amputation, like Benivieni, he relied upon the cautery, and mentions ligature only in the case of tying an uncut vessel before dividing it, as for example Antyllus did in aneurysm. The current fame of Vigo is that he first wrote of the wounds

of firearms, though a bare priority is said to belong to Cumanò (p. 53). In respect of a controversy of which I shall have to speak more fully, John of Vigo held that the wounds of firearms were scorched and poisoned wounds, and therefore to be purified by the cautery and injections of boiling oil.

Although even in Italy pus kept in favour with physicians and surgeons alike, till Lister swept it away,¹ yet in the sixteenth century, as in all periods of the history of Medicine, surgery, being conversant directly with nature and fact, was before inner medicine to receive the inspiration of the new methods of personal experience and free inquiry. Indeed the unscholarly training of its practitioners saved them from the tyranny of the letter; while the enlightenment of truth slowly compelled the regard of their haughtier fellows. In all countries, Italy excepted where from Salernitan times onwards scientific surgery had always been held in honour, the barbers, the bone-setters and the cutters, the most intimate of the servants of nature, gained upon the superior surgical persons of the colleges, and demanded admission to their ranks. All honour to them; for these humble and faithful ministers of such medicine as they knew, tended the lepers and the syphilitic, and in times of pestilence stuck bravely to their posts when their

¹ Professor Howard Marsh makes the following note on this sentence:—"I do not think surgeons down to Lister (say Lawrence, Brodie, Paget or Syme) favoured, or, consciously, took steps to procure pus. But, not seeing how to avoid it, they desired 'healthy pus,' 'pus laudabile' instead of sanious or ichorous pus. They were always glad (even if surprised) when none formed."

betters stood timorously aloof, or even took to flight.

When we turn from these general considerations to consider the life of Franco, the surgeon who shares with Paré the glories of French Medicine of the sixteenth century, we shall see how it was from the depths not from the heights that Medicine was fed; from the springs not from the sky, which was as brass. There is a well-known passage in the Oath of Hippocrates, a passage well known not only as a part of that great injunction, but also as a somewhat unintelligible part: that, namely, in which the aspirant is to promise that he will not cut for stone, but will leave this operation to a peculiar class of practitioners. That this warning signifies surgery to be a calling inferior to medicine is, as Littré well says, an opinion devoid of the smallest probability, one which is belied by the whole of the Canon wherein the Greek physicians appear constantly as practitioners of medicine and surgery alike. And in so high a discourse it is difficult to accept the explanation of Franco that the counsel was one of vulgar prudence; that Hippocrates, and after him Galen, not despising either the work or the workmen, yet shirked undertakings which were full of risk and exposed the surgeon to calumnious tongues. Franco murmurs indeed that if a patient die under medicine the faults of the physician are laid to the score of the imperfection of nature; but that if he die under operation the surgeon is an executioner or a murderer, and not rarely has to take to his heels. Such are the words of the

boldest of the responsible surgeons of the sixteenth century. Franco, like Paré, was no clerk; he came of a class lower even than that of Paré and the barbers, that class, mostly wanderers, of bonesetters, oculists, plastic operators, and cutters for stone and hernia, of whom I have often spoken. Seeing that until the time of Gersdorff and Paré the regular surgeons, if they ventured at all upon the larger amputations, postponed them till, to the certain witness of the bystanders, the patient was moribund, we cannot wonder that, even from the time of Hippocrates—to say nothing of the Egyptians—the dangerous ventral operations, and those on the eye which but too often were swiftly disastrous, fell into the hands of peripatetic craftsmen, runagates Gale calls them, men usually of low origin, ignorant, reckless, and rapacious. These travelling surgeons of the short robe operated but too often with great brutality,—and usually got out of reach before the issue. If the issue were fatal, or indeed without substantial relief to the patient, they stood a good chance of paying with their skins. In Dr. Henri-Maxime Ferrari's interesting book *Une Chaire de Médecine au XVme siècle* are some anecdotes of these operators, and of their mode of life. One of them, who by an operation on the eye had failed to relieve the pain of a certain lady (who would seem to have had a glaucoma?), was pursued in the night by her infuriated husband with a naked sword in his hand.

As the truss was a very clumsy instrument, at any rate till the end of the seventeenth century,

the radical cure of hernia was in great demand.¹ In the district of Crotona twenty-seven families of these special operators flourished for a long period. In later times they got more culture, did substantial work for Medicine, and were called to great nobles even down to the eighteenth century.² One of them was surgeon to Sixtus IV. in Rome, and to Francesco Sforza in Milan. But from the time of Franco no important book came again from such operators till that of Durante Scacchi of Urbino in 1596. That Calabria was a chief nursery of these cutters may possibly signify that the craft had survived from the days of the Greek³ "Periodeutes" who pretty surely travelled to the Doric Hellenes of Magna Graecia.⁴ Now it is the chief merit of Franco that he brought these operations within the lines of responsible surgery, raised them again to the standard of Celsus, and thrust them into the ken of Paré and Fabricius.

The illustrious Provençal surgeon—"ce beau génie chirurgical," as Malgaigne, in declining the task of entering upon so full a life, calls Franco,—was born about 1503. It is a note of his fearless and penetrating spirit that he was a Huguenot, and

¹ So far as I remember Franco never even mentions the truss. Fabricius of Hilden (p. 97) was perhaps the first surgeon to bring the instrument into a practicable form.

² Cf. Fabbri's *History of the Lithotomists and Oculists of Norcia*. Bologna, 1870.

³ Of operation for hernia we have no record in the Hippocratic canon; if Praxagoras of Cos performed it (cf. *Caelius Aurelianus*, *Acut. morb.* iii. 17) unfortunately the texts are not convincing.

⁴ It is difficult here to avoid a passing allusion to the survival of some precious rivulets of Greek art and Greek language which had not dried up in Calabria in the time of the Pisani.

for his religious opinions was driven to Switzerland.¹ We may wish we had his concise opinion of the mock St. Côme, founded at Toulouse in 1517, whose "mires" (myrrhes) or "médecins chirurgiens," determined not to be behind the Paris body, declared "qu'il n'y avait rien de plus vil que la chirurgie," a "rifiuto" which the students joyfully acclaimed.

Franco began as an apprentice to an operating barber, and to a hernia specialist. He had no more "education" than Paré or Würtz, and he was spared the misfortune of a speculative intellect. Dr. Alezais² describes him as a "membre de St. Côme à Paris," but this is certainly incorrect. He picked up some anatomy, educated himself by observation, experience and manipulation, and as a simple operator or "Master" won considerable renown. As upright and modest as Paré, though he never attained Paré's social position, he submitted to work under the physicians, taking his quiet revenge in the remark that they did not know enough to distinguish good surgery from bad. Nicaise³ says roundly "No surgeon made such discoveries as Franco; for hernia, stone and cataract he did much more than Paré." In comparison with Paré Haeser treats Franco somewhat slightly, for not only did Franco bring the operations for hernia (whether for strangulation or for radical cure), lithotomy, diseases of the eye,

¹ The Waldensian massacres took place in 1545.

² *Les anciens Chirurgiens et Barbiers de Marseilles*, 1901.

³ No longer do I write *Mons. Nicaise*, as unhappily this able historian at the height of his attainments has been taken from us.

and plastic operations into the field of legitimate Medicine, but by the great advances he made in the technique of these several departments he did so with great effect. In asserting that no surgeon made more advances than Franco, and few so many, Nicaise is probably right. His compatriot of Chauliac had much influence upon him, but Guy had not made much adventure into these specialist fields of surgery; he had not invaded the monopolies of the "vagabonds," nor contended against their ignorance and audacity. Whether from sheer ignorance, or the brutality of habit, it had been the custom during the Middle Ages, and down even till the middle of the seventeenth century, in operating for hernia—and in spite of Celsus' clear distinction (vii. 21), hydrocele and sarcocele were not too carefully discriminated from hernia—to sacrifice one or even both testicles; an abuse against which Franco took successful precautions, and proved that the canal could be closed and the ring sutured without castration. In irreducible inguinal hernia he distinguished between opening and not opening the sac, and described adhesions of sac and intestine. From him indeed dates the rational operation for strangulated hernia,¹ and in strangulated scrotal hernia he founded the method. Paré, and after him Petit, condemned the

¹ The earlier practice of the specialists was to puncture the skin and bowel, and after recession to apply the cautery to the skin. Guy saw 30 cases so treated. Fabricius inverted the patient and shook him by the legs. We must judge gently of such primitive methods as these; even Paré spoke favourably of reducing hernia by strewing iron filings on the tumour, and administering lodestone internally.

ablation of the testicle,¹ a procedure however which many surgeons thought quite good enough for priests; and for these advances he gives credit to Franco, though Fabricius does not even mention them. But Paré did not himself attempt such operations; he did the best he could with long recumbency, and the local use of bandages, plasters, strong astringents (such as dragons' blood), or cauterising and cicatrising agents. In children it seems that, with the help of nature, such methods were not altogether fruitless; but in spite of the improvement in trusses by both the surgeons distinguished under the name of Fabricius² and by later surgeons, the Council of Zurich even so late as 1693 had to forbid excision of the testicle, and indeed all herniotomy save in urgent cases.

Stone must have been a very common disease in the Middle Ages; and cutting for stone, though surrendered to specialists, was in rather better hands than herniotomy; for in large part, as I have said, it became the profession of responsible families of which the Collots, whose dexterity Paré commended, were the chief. These men were not all charlatans by any means,³ and in their hands no doubt the

¹ As Franco's book on hernia was published under the approval of the Chirugiens-jurés of Paris and in two editions, Paré must have known it well.

² Fabrizio carried Paré's improvement of trusses so far forward that he reduced the operations of one Italian family of hernia cutters from 200 to 20 in the year. Very early in the sixteenth century Benedetti, a Professor of Perugia, adopted a Spanish method of saving the testicle. (See Fabbri's history of these specialists. Bologna, 1870.)

³ Franco speaks of the "Maitres de bon aloi qu'il faut distinguer des periodeutes charlatans." The more respectable of these peripatetics seem to have confined themselves to one country or district (*vide note, p. 73*).

operation gained both in method and in skill; though as such a family depended for its reputation on the possession of secrets real or supposed, our records of their methods are few and insufficient. At this time no surgeon graduate, not even Paré, as I have said, dared to meddle with the operation. The method of Celsus was with the finger in the rectum to cut the perinæum transversely on the stone without a director, and to hook the stone forwards; for this purpose John of Gaddesden used forceps. But such a blind method could not answer well, except perhaps in children. The next step, to pass a catheter or sound into the bladder, is attributed to an unknown surgeon of Genoa; and sounds and catheters of wax, tin, or silver were no new things at the beginning of the sixteenth century. Stricture of the urethra however in these centuries was even commoner than stone. Franco, who did more for the operation than any surgeon of the sixteenth century, work indeed of permanent value, took the lead in the lateral, and also in the high operation—that is in opening the bladder for large stones directly above the pubes, a method which until his day was disliked. He pictured soft sounds of lead, and many catheters, some with stylets. Sanctus, a Neapolitan surgeon and pupil of Vigo, fully described the median operation on a channelled director, thitherto a secret. This director, or “itinerarium,” Collot got hold of, and showed to Paré. Franco, who seems to have known some Latin, probably got it directly from Sanctus’ *Libellus aureus de lapide a vesica per incisionem*

extrahendo, 1524; and as Franco's books were well known in Paris (p. 76, note) Paré probably had this higher authority in its favour. Malgaigne confesses that Paré was far from doing justice to his great contemporary, who even in hare-lip was more precise than Paré. However literary property was scarcely recognised in those days, and Franco in like manner lifted much of his knowledge of syphilis from the *Des bubons vénériens* of de Héry, to whom neither Franco nor Paré seems to have been very generous. Paré defends plagiarism by the metaphor that every candle must be lighted from another candle. Fallopius was perhaps the first to recognise literary honesty, at any rate in Medicine.

Unhappily in lithotomy the director fell into disuse, and tearing and errant divisions of the parts resumed their vogue. Even the Collots were probably rough, bruising operators; and such was grievously the case with the celebrated Frère Jacques, who practised the lateral operation with prodigious renown. To him I am tempted to turn for a moment in passing, although by his later date he lies out of my proper limits. Jacques Beaulieu, or Frère Jacques, was born of poor parentage in Franche Comté, in 1651. He was a great friend to the poor; but he was uncouth in manipulation, and his instruments were clumsy. On his European celebrity he received a friendly invitation to Paris from the all-powerful Félix, and exhibited the lateral operation there; but things went ill with him, for out of 65 operations he had 25 deaths, and only 19 cures. At that time at any rate he knew no anatomy; he

used to cut into the body of the bladder beyond the prostate, so that urine was extravasated into the cellular tissue of the pelvis; and he often wounded neighbouring organs and blood-vessels. At a later date, having learnt some anatomy, improved his instruments, and introduced the staff, he returned to Paris, when he is said to have operated on 38 patients without a death. By care and skill Rau of Amsterdam, Cheselden, and Hawkins reduced the mortality of Frère Jacques' operation—in the hands of Cheselden to 7·5 per cent. Rau, according to John Bell, behaved in this matter with duplicity towards Cheselden.

When Franco steps beyond his surgery he becomes, as Guy in like manner, as blindly galenical as the pure physicians. He does not even suspect that Galen had not to deal with lues. In the Middle Ages ophthalmic surgery also, in the hands of barbers and wayfarers, had fallen into sad decay and abuse.¹ For eye surgery however the ancients and the Arabs had done a good deal, and even John XXI. something; in Bern and Lausanne an illiterate practitioner like Franco would get access to Celsus, and to Paul or Albucasis. Franco practised his eye operations on animals, and on dead bodies of men; and in the treatment of cataract is full in his instructions and precautions.

I cannot make more than a passing reference to the large and interesting subject of plastic opera-

¹ The best insight into the state of this department of surgery in those days is to be had by perusing the treatise of Bartisch Court barber, cutter for stone and oculist, in Dresden (1535-1606). It contains good figures both of diseases and instruments.

tions which, after the times of Celsus and Paul, became the industry of specialists. The Brancas of Catania, who were celebrated nose restorers in the fifteenth century, seem to have got their knowledge from some stray MS. of Celsus. In the fifteenth century these operations had been many and important, probably because of judicial mutilations, free fighting, and syphilis. The material for regeneration was generally taken from one arm, which was bandaged to the face for some weeks. These operations fell into disuse till Tagliacozzi of Bologna rediscovered them two hundred years later. Paré and Fallopius rather ignorantly denounced them, and the clergy looked askance at such restorations, as a blasphemous invasion of the prerogatives of the Creator. After Tagliacozzi's burial, in the Convent of St. John the Baptist in Bologna, his cries in everlasting torment so disturbed the holy peace of the nuns that there was nothing for it but to howk his body out of its tomb and to restore it to unconsecrated earth. Even in 1742 that sublime body the Paris Faculty forbade such creative adventures altogether.

The very eminence of Ambroise Paré encourages, if it does not command me, to be content with few words of commemoration. If in some respects perhaps Paré may not be lifted far above his great Italian contemporaries, such as Carpi, Maggi, or Botallo, yet in a comprehensive judgment he surely stands alone in the surgery of the renaissance as an independent, original and inventive genius, and as a gentle, masterly and true man. Himself of

humble origin he won for surgery in France a social place and respect it had never attained before. Born in 1517, he became a barber's apprentice in the Hôtel Dieu, whence he was called to join the campaign of Francis I. against Charles V. As he could not write a Latin thesis, his admission to St. Côme was of course opposed by the Faculty; but Paré stoutly and sagaciously declared that the vernacular¹ tongue was essential to the progress of Medicine; sagaciously, because the rise of the vernaculars from the fourteenth century onwards was as vital a factor in science as the formation of a latin medical prose had been.² Riolan the elder, who had taken part in the opposition to Paré, wrote a tract in 1577 with the following insolent title: *Ad impudentiam quorundam Chirurgorum qui medicis sequari et chirurgiam publicè profiteri volunt pro dignitate veteri medicinae apologia philosophica.* To such inflated vanity the medieval "pure" physician lifted up not his mind only but his very soul. At this time, be it remembered, Paré was sixty years of age, and Surgeon to the King.

The first subject which comes into our thoughts with the name of Paré is that of the ligation of arteries; and you will scarcely desire me to pass

¹ Gale also wrote in the vernacular. The favour shown in the fifteenth century by the modish house of Este to the Italian vernacular (to Boiardo for example) gave a new impulse to its use in literature. The humanist, then as now, was fastidiously averse to vulgar progress. When, at Lorenzo's advice, Bernardo Rucellai invited Erasmus to answer his letters in Italian, Erasmus declined —lest he should spoil his style!

² One is tempted here to remark that Paré was testifying for his mother tongue seven centuries after Alfred, the pontiff of the vernaculars. On the formation of medical latin *vide* p. 25.

on without some discussion of it. I am often surprised to see, even to-day, the invention of the ligature attributed to Paré, whose surprise, if our journals have an astral shape, must be greater still, seeing that he himself, to justify an apparent innovation, refers the ligature to Galen. He says the ligature must have been taught him by the special favour of the sacred Deity, for he learned it not of his masters, nor of any other, neither had he found it to be used at any time by any. Only he had read in Galen there was no speedier remedy for stanching blood than to bind the vessels through which it flows. (Johnson's Edition, 1634.) The attribution is of course a legend. Malgaigne discreetly claims no more for Paré than the application of the ligature from wound-surgery to amputations; but I have implied already that even this claim goes beyond the truth of history. I must remind you once more that in all ages until the time of Paré the surgeons, for very intelligible reasons, shirked the larger amputations. Gersdorff indeed, a great surgeon of Strassburg of the previous generation, had rejected boiling oil and the cautery and, using only a styptic of hare's fur and white of egg, had performed two hundred of such amputations. He enclosed the stump in a bladder. The first picture of an amputation—it represents that of the leg just below the knee—is in Gersdorff's book (A.D. 1528). Yet it would be no great exaggeration to say that even to the time of Petit, who in the middle of the eighteenth century substituted the screw tourniquet for bandages

tightened with sticks and stones, amputation of the larger limbs, save in gangrene, was avoided as long as possible, and only too often longer than that. Celsus speaks of the ligature as an ordinary method in wounds.¹ From Oribasius we learn that Archigenes of Apamea tied vessels even in amputation, after fixing a tight band at the root of the limb.² In the Middle Ages Yperman (p. 35) and others—even Roger and Roland—knew the use of the ligature, and Yperman indicates the method as proper for arteries. It seems probable that, unless performed with modern nicety, secondary hæmorrhage must have been frequent under ligature, especially on the battlefield;³ indeed so late as 1773 Petit discarded the ligature, as Franco and Fabricius had done. Although Guy had endeavoured to improve amputation, by drawing up the skin and muscles, he never mentions ligature; he used the red-hot knife and styptics. Paré however tells us plainly enough that he undertook his experiments with the ligature, and his improvement of this means, because of the general experience of surgeons that the cautery, scalding oil, and styptics such as rabbit's fur, aloes, and white of egg so fouled the wound, and destroyed the flesh, as to set up fever and to spoil the flaps which were then

¹ "Quod si illa (medicamenta) quoque profluvio vincuntur, venae quae sanguinem fundunt apprehendae, circaque id quod ictum est, duobus locis deligandae, intercidendaeque sunt, ut et in se ipsae coeant, et nihilominus ora proclusa habeant."—Lib. v. c. 26, § 21.

² Paul on removal of tumours says "*τὰ μὲν ἀγγεῖα διασφίζομεν.*"

³ The best description of the ligature to be found in the seventeenth century is by Fallopius in the second volume of the Frankfort Edition of 1660, p. 210.

being designed and brought into practice. In contaminated wounds the cautery often acted no doubt as a purifier, as suppuration did (p. 30); but the means were indirect, precarious, and fraught with incidental mischief. It is a more intelligent service to a great man to point out how this detail and that of his invention were no mere incidents, but steps in a large reform of method; a reform which developed itself in Paré's hands on the introduction of firearms, whose ravages could not be covered up with galenisms.

If John of Vigo was not the first to mention, it seems he was the first to discuss the wounds of these new instruments of war. In a translation of Vigo's *Surgery* of 1514 is a chapter entitled "*Plaies faites de hacquebute, de bombardes et d'instruments semblables*" in which we read that Vigo shared the belief of the surgeons who first wrote of gunshot wounds, such as Brunswick and Gersdorff, that these wounds were envenomed burns; so that the chief aim of the surgeon should be to destroy the dead flesh and to neutralise the venom. To this end Vigo used the actual cautery, where possible; but for penetrating wounds the injection of boiling oil was more effective and convenient.¹ Berengar, Paracelsus, and Würtz did not accept the element of poison, but that of scorching only, and were content therefore with cooling methods; of their opinions, however, Paré had no knowledge.

¹ I ought perhaps to say here that long before shot wounds were known boiling oil had been poured into any poisoned wound, as of venomous bites and the like, as the reader will readily discover, for instance, in Guy's chapters on wounds.

After a long verbal strife, the next step was made by Maggi, who in a series of novel and interesting experiments, published in 1551, discomfited Vigo by firing balls at bags of gunpowder which did not explode; and arrows tipped with wax or sulphur, which, however swiftly shot forth, respectively neither melted nor ignited. Thus he disproved the combustion hypothesis also. But to return to Paré: the story goes that on the evening of an engagement Paré administered the "first aid" of boiling oil, as an antidote to the venom, to all those injured by gunshot save one, for whom the supply fell short. After tossing on his couch with regret and apprehension, Paré rose betimes to see this patient, in the hope no doubt of being enabled to provide boiling oil for him also: but to his amazement the unscalded limb was the best of the bunch; the patient had passed a fair night, his wound was not angry, swollen or throbbing, as the others were; nor was he feverish. From this time the receptive mind of Paré perceived that venom and burn were figments both, and that a gunshot wound was just a contusion or a comminution like another. So severe however were the injuries of gunshot, so frequently did these contusions become septic, even in the greatest seigneurs, and so rife the wound fever which, at the siege of Rouen, Paré attributed in part only to a "malignant atmosphere" and in part to putridity of the wounds, that he determined to devote himself to the perfection of a more timely method of amputation. It was as a part then of a great reform of method

that Paré was led to improve the ligature; his most orthodox patients proved not unwilling to forego boiling oil and the red-hot knife, and a successful early amputation of a smashed leg, at the siege of Damvilliers in 1552, placed his new method in safety.

Upon the many other contributions of Paré to surgery I cannot dwell; such, for example, as his ingenious method of detecting the course of bullets by placing the injured man in position as he was when he was struck—a plan first adopted by him in a consultation on the case of M. de Brissac. By this device Sylvius was so much pleased that he urged Paré to write his treatise *Des playes d'hacquebutes* (1546).¹ Sylvius (Jacques Delboe, or Sylvius the first) was the most erudite anatomist of the medical schools; yet Paré in his illiteracy had over him, as Palissy, whose demonstrations in his museum were attended by Paré, had over his learned audience, the ineffable advantage that when Hippocrates, Pliny and other great ancients came by translation within his reach, he read them in the unrefracted light of one practised in immediate contact with nature herself; and thus, without servility

¹ Vesalius, born three years before Paré, was also a pupil of Sylvius, who by the way was afterwards terrified to see what sort of a wildfowl he had hatched; but there was a great gulf between a lettered graduate and a barber's boy. Malgaigne reminds us that Vesalius' first anatomy and Paré's first tract on gunshot wounds were likewise published at the age of twenty-eight. How Paré pounced upon Vesalius' anatomy, how he used it "to verify his own experience," and how he prefixed to his *Surgery* a compendium of it, which during the next hundred years did more than the large and academic work of Vesalius himself to vulgarise the new anatomy, is too well known to be told again at large.

or prepossession, assimilated what he saw was masterly in them, as for example in the "Fractures and Luxations" of the Canon, upon which Paré drew largely. But it was probably before he read Hippocrates that Paré described for the first time fracture of the neck of the femur. He did not hesitate however to criticise Hippocrates, nor to differ frankly from him, or from Celsus, Paul, or Albucasis, if occasion required. He writes "Il ne faut pas s'endormir sur le labour des anciens comme s'ils avaient tout su ou tout dit." As Guy was the last and greatest surgeon of the arabists, so Paré was the first and greatest of the renaissance; Guy was the champion against medieval tyrants, Paré against the humanists and the Greek tradition. Nor was Paré great on the positive side of progress only; he was no less resolute in confutation of fabulous lore. If he believed in his puppy dog fat—and how could he resign a secret remedy which had cost him so many prayers!—he denounced, with an audacity which in our tepid and sceptical times we can scarcely appreciate, the bogus virtues of mummy and unicorn. As great personages would marvel that he had not administered mummy in their lacerations,¹ Paré was aroused to indite his opinion of the stuff; and the King must have been annoyed to read farther that the horn of the unicorn at St. Denis, for which he had refused 100,000 crowns, was but an old woman's charm.

We parted from Henry of Mondeville carrying

¹ "Mummy," says Francis Bacon, "hath great force in staunching of blood, which may be ascribed to the mixture of balsams that are glutinous."

with us a pious and dignified sentiment; let us take leave of Paré with these words of his in our ears:—"You will have to render account not to the ancients but to God for your humanity and your skill." Was Paré the first modern surgeon to put humanity even before skill? To us the barbarous practices of medieval surgery seem ferocious, yet we may reflect that in those violent days men's nerves were mercifully blunted, even, let us hope, the nerves of the patients.

In Germany, for all its meddlesomeness in Italy, Medicine, save in the debatable lands of Alsatia and Switzerland which drew some enlightenment from France, was in a barbarous condition. The manuscripts in Germany were few, and its universities, potent as they were to be in the emancipation of thought, were of later foundation than those of Italy. Germany had not even a St. Côme; and it would seem that, in the fourteenth century at any rate, there was no regular apprenticeship. Thus German surgery was grossly artisan, and therefore barbers and bathmen¹ flourished ex-

¹ The virtues of mineral waters and baths never lost the high repute attributed to them during the Roman Empire. I have before me a handsome thick folio in double columns *De Balneis*, published by Giunta in 1553, which is but one of those collections of treatises in the department of Medicine of which so many were published in Venice at and before this date. Some of my readers may remember Albert Durer's plate of a man's bath in a German town early in the sixteenth century. Becker (*loc. cit.*) includes bathmen among the practitioners, regular and irregular, of Hildesheim ["Aerzte und Wundärzte, Bader und Barbieri, Quacksalber, die Alexianerbrüder (a kind of sick club) Aerztinnen und Hebammen, und sogar—der Schinder!"]. Aachen was the fashionable spa in that district.

ceedingly. Nevertheless even in the fifteenth century, whither we may turn back for a moment, some great surgeons had arisen in Germany; the earliest of them who deserves remembrance was Heinrich von Pfolspundt—Pfalzpaint, in Bavaria, south of Nuremberg—the manuscript of whose *Bunth-Ertzney* had the fate of Yperman's treatise; written in the middle of the fifteenth century, it fell into oblivion until the nineteenth, when it was discovered in Breslau, and was published in 1868 by Haeser and Middeldorpf. Heinrich, like Paré and many of the greater surgeons, was an army doctor and saw much service; he was of noble family and seems not only to have served but also to have studied in Italy; yet he was unlettered, uninstructed, and, as it would seem, knew only his mother tongue. As a wound surgeon ("Schäden und Wunden") he left minor surgery to the barbers, and the larger operative work to the cutters ("Schneid-Aerzte"); on the other hand he had learned "from a foreigner" the guild secret of making new noses (p. 80). His aversion from the vulgar herniotomy was a rational aversion; Pfolspundt appears indeed to have been the first considerable surgeon to protest against the barbarities of such specialists (*vide* p. 75). In an appendix he deals with some inward maladies. Heinrich was no anatomist, and in fractures and luxations a mere empiric; moreover, in common with most or all of his contemporaries, he was helpless in compound comminuted fracture. Still he was a shrewd, resourceful and not uninteresting person,

who divided wounds into fresh and foul; and although, even in fresh wounds, he was a "suppurator," and used turpentine and the like to promote pus, yet he discarded tents, except for sinuses. For hæmorrhage he does not mention the ligature; he employed cold applications, and styptics on tampons. In arrow wounds he had a large experience; he was opposed to too much haste in extracting the weapon, and to too early a use of the suture. Of gunshot wounds he makes no mention. As did the surgeons of all previous ages, he placed much trust in "wound drinks," such as ptisan of Artemisia and so forth. He devotes a section of his book to the anæsthetic inhalation of Theodoric, and recommends its use.¹

In the history of the part of Germany in European surgery we are apt, in the light of his physical and chemical excursions and of his many-sided character, to forget that Paracelsus (born 1491) was a surgeon, and no inconsiderable one. Had this extraordinary man been endowed with a little patience he would have been a leader in wound surgery, though, like Würtz, and unlike Gersdorff, he was not an operator. Paracelsus pointed out not only the abuse of the suture by the surgeons of the day,² but also that suppuration is bad healing. If left to herself, he declared, nature heals wounds by a "natural balm," a phrase

¹ Guy of Chauliac tells us that sponges were impregnated with a mixture of opium, henbane, hemlock, lettuce and other drugs and dried in the sun. Before use a sponge was dipped in hot water, and the patient then respired the vapours from it till he fell asleep.

² John of Vigo used the suture extensively, but always left an exit for the pus (*vide* p. 9).

which Paré adopted (p. 31). In his *Grosse Wund-
arznei* he says he began at the surgical because
it is the most certain part of Medicine; and time
after time he rebukes those who withdrew medi-
cine from surgery. The unlearned, he says, speak
of "surgical diseases," which is unreasonable, for
Medicine (Arznei) is one (einerley). Called to
the Chair of Medicine and Surgery in Basel,¹ he
burnt Galen and Avicenna in the marketplace,
lectured boldly in the vernacular, and declared
reason based on experience of nature to be better
than authority. Nature, he says, has her plan, and
the physician's duty is to see fair play, and to keep
the ring for her (pp. 42 and 97). Conrad Gesner
(b. 1516), the naturalist and physician of Zurich,
the friend of Caius,² in his wise way saved what was
good in this revolt, and wrought at the ancillary
sciences. To the dawn of natural science, however,
the apostle of mystics was blind or waywardly
averse. Rightly but too exclusively Paracelsus laid
stress on function; as to every several function
he gave its "Archaeus" so for him every disease
was an entity, and every cure was to consist in an
arcanum against the Archaeus. He had genius, but
his experience was crude and precipitate.

Brunschwig (born 1497), the first of the great
Alsatian surgeons, was, until the discovery of Hein-
rich of Pfolspendt's manuscript (written thirty-

¹ It is interesting to remember that in the sixteenth century, Franco also was practising at Berne and Lausanne, and Würtz at Basel. Wittenberg was not founded till 1502.

² Whose *History of English Dogges* was composed for Gesner's *History of Animals*. Würtz may have met Caius (p. 94).

seven years before his own work), regarded as the father of German surgery. He was a barber, but had received a good education in Bologna, Padua, and Paris. Like Würtz he was a wound surgeon and bone-setter, and undertook no large operations save those amputations which, in the case of the severest injuries, became inevitable. For Brunshwig, however, as later for Paré, gunshot wounds compelled operative procedure more into prominence. He was indeed the first surgeon to enter upon the surgery of gunshot wounds with any fulness or precision. He too held that a gunshot wound was a poisoned wound; and, to eliminate the poison by free suppuration, used the medicated tents, or, in case of through penetration, the setons, which were to arouse the angry antagonism of Würtz. If the ball were out of reach in the body, he promoted suppuration by poultices, turpentine and other balsams; and seems to have hunted for the missile with a kind of duck-billed speculum. No wonder erysipelas and phagedæna were rampant. When he was driven to amputate a large limb he bound it above and below, drew up the skin before incision, and applied boiling oil or the cautery to the stump. With Heinrich he objected to anæsthesia by opium, and used the narcotic inhalation of Theodoric, which had some vogue all through the Middle Ages (p. 90, note). Like all the German surgeons he wrote in the vernacular.

I would remind you again how large and various was the experience of the battlefield, and how fertile the blood of warriors in rearing good surgeons.

As Yperman and Paré, Gale and Wiseman, Maggi and Botallo, so Brunschwig, Gersdorff and Würtz won their spurs in Papal and Royal wars, as the crusading surgeons had done from the Council of Clermont to the fall of Acre. Brunschwig, however, leaned heavily on Rhazes and Guy, and even with gunshot surgery did not get very far; a greater reformer in this new military surgery in Germany was Gersdorff, also an Alsatian, a man of great experience and originality, and evidently a good mechanic. As did Paré and Wiseman, in amputation Gersdorff made great use of the constricting band, to blunt the pain as well as to check hæmorrhage. He did not sear, but used a styptic of his own, and covered the stump with a bull's bladder. In a more and more complete retraction of the tissues before incision he made a great improvement upon the old "sausage cut." If he probed gunshot wounds too eagerly, he did not pour in boiling oil. The works of both Brunschwig and Gersdorff are illustrated, and not by drawings of apparatus only; in both volumes are large and spirited pictures. In one of the illustrations of Brunschwig's *Surgery* (Strassburg, 1497), for example, a man is laid upon a couch with many and grievous wounds upon him; one of them being an ugly compound fracture of the right leg. A woman and two men are deliberating on his case. In Gersdorff's *Field-book of Wound Surgery* (the Strassburg edition of 1528) is a lively scene of an amputation of the leg, in which however it must be admitted that the cut is shown very much after that of the "sausage." In another excellent woodcut two surgeons with some

mighty probe are digging for an arrowhead into the breast of a man seated on a three-legged stool. In the near distance an animated fight is in progress, and cannons and arquebuses, as well as spears, pikes and crossbows, are in full activity.

In Germany even of the sixteenth century there were no medical schools, not even of anatomy (p. 88). Thus Felix Würtz, if like Franco and Paré he had good fortune in escaping a scholastic education, was lucky also in the enjoyment of the more liberal education of Gesner's friendship. Gifted with an independent and penetrating mind, and aroused by the fiery disputes of Paracelsus, he is as fresh and racy as Henry of Mondeville had genius enough to be in spite of the schools. Like all his compatriots he wrote "*in sermone barbaro*"; and for its originality and conciseness Würtz's *Practica*, published in 1563, stands in a very small company. Had he known as much anatomy as Paré, his defect in which he bewails, he might have advanced in operative surgery and become as great a man; for his clinical advances were both new and important. It is in the freshness and originality of his mind and in his freedom from scholastic convention, that he reminds us of Paré. Würtz protests against the kind of examinations for practice held in some cities, where candidates patter off cut and dried phrases like parrots, and apprentices "play upon the old fiddle the old tune continually." Surgery, he says, is a painful calling, and is not to be learned by sitting on a cushion at home. Who would order a picture of one who prates much of colours, but

scarce knows how to hold a pencil? Würtz, being, as I have said, a wound surgeon, does not venture so far as Gersdorff in amputation, and the ligature he never mentions; but he abhors barbarous blood staunchers, though in case of amputation of the thigh¹ hot irons must be at hand. He has seen no reason to believe that bleeding is of use for "revulsion," nor that it "draws away humours from the head"; it is a remedy to be used opportunely and discreetly. Würtz is urgent on cleanliness; clean hands, no hanging sleeves. He protests against probing² and tenting, and dislikes poultice messes; but as to suppuration, well, in spite of Paracelsus, it must be: he has never seen a severe wound heal without it. As in any wound the virtue of coction is diminished, is not suppuration therefore necessary as a cleansing process? (pp. 30 and 84). Still practice is better than conjecture, and if neither he nor Paré attacked suppuration in principle as Theodoric and Henry of Mondeville had done, Würtz, by setting his face against cataplasms and grease, made for progress. Discreet as Paré and Würtz may themselves have been, yet the fidgety manœuvres, the probes and the plasters, the tents the salves and the setons, the handlings and the gropings, the meddlesome dressings, two or three a day, as the indications were incarnative, mundificative, maturative, cicatrisative, or consolidative, held on their fantastic and mischievous way.

¹ Perhaps the first definite mention of this grave operation?

² "If there is more than one surgeon each of them must thrust his iron up and down in it, disturbing the healing balm, which should lie like a crystal on a clean wound."

Würtz's chief title to fame, a fame far less ripe of course than that of Sydenham but, as it seems to me, not unworthy to be remembered beside it, lies in his clinical acumen; and especially in his development of the Hippocratic doctrine on wound infections and their results; a doctrine which in arabist tradition was embedded in a partial and fragmentary way. He publishes, as Paré did, and as Salicet and Lanfranc had done, a large and various collection of cases. Watch, he says, and learn to read any sign, be it never so mean; for every day one may discover new secrets of nature. Würtz divides wound fevers into three classes:—First, those which set in with rigor, heat and sweating; secondly, with pain in the wound followed by repeated chilliness; thirdly, with restlessness and twitchings, the chills being less distinct. He says definitely that these disasters are due to absorption of poisons from the wound.¹ His description of diphtheria in throat or wound,—sometimes first appearing in the one, sometimes in the other,—when “prunella,” as it is called in the only copy I had at hand,² may be stripped off like a rag, is very remarkable. Yet on the curious German myth of “joint-water” he is even more didactic and inexplicable than others of his compatriots of the period; a myth which that “ever angry” man Johann Lange of Limberg demolished at last. No surgeon of his day, or before it, had given the attention which Würtz

¹ For a full account of these observations I refer the reader to Billroth's *Historische Notizen über die Beurtheilung und Behandlung Schusswunden*, 1889.

² An English translation by A. L. Fox, London, 1656.

gave to conservative surgery. "Never, if you can help it, bereave a man of any part; for God's grace may be great upon it beyond the expectation of men." If this rule be more pious than definite, I may refer to his fuller details of splinting and bandaging joints, fingers, and other movable parts, in such positions that, if they must become stiff, they may give the least inconvenience.

Of the French Pox Würtz notes its peculiar influence on concurrent diseases and wounds; and that surgeons use mercury for it as indiscriminately as if mercury "were a saddle for any horse." He tells us not to thwart but to follow nature, "for she is as a strong river." He claimed truly that he had written no big book copied from those of his forerunners — for "naught will still be naught though practised for a thousand years"; that he had trimmed himself with no strange feathers, that he wrote only what he had made trial of, and that he had concealed nothing of what was known to him.¹

In this period of German surgery it is convenient to mention that learned and skilful physician Wilhelm Fabry (or Schmidt) of Hilden near Cologne (1560 - 1634), usually known as Fabricius Hildanus; though he belongs in large part to the seventeenth century. He practised in Switzerland, was "Stadtarzt" of Bern, was associated with the Platters in Basel, and raised surgery in Germany to such honour and social con-

¹ I regret that Würtz's appendix on the management and cure of little children falls wholly outside my subject. It is full of wit, shrewd practice and common-sense.

sideration as to deserve the name of the German Paré. The several parts of his *Observationum et curationum chirurgicarum centuriæ* were published at Basel from 1606 to 1646. With him we find not only that cases are published, as they were by his ablest predecessors (p. 33), but that his book consists of them; and we note, as in the Penta-teuch of that other and greater Fabricius, "de Aquapendente," that we have entered upon a new kind of surgical literature. Fabry was far more than a "wound surgeon"; he operated boldly, and in the whole field of surgery. Like Vesalius he used the hot knife, which Paré had discarded; and in Gersdorff's fashion put the stump in a bull's bladder. Flaps were not adequately designed till a later date, but with a leather collar or compressor he carefully drew up the soft parts before dividing the bone, whereby also he prevented hæmorrhage. Thus he successfully amputated above the knee, but perhaps not—as his latest biographer alleges—for the first time (p. 95)? For hæmorrhage he sometimes cauterised, but sometimes he drew out the vessel with forceps and tied it with ligatures of flaxen thread. Another hundred years were to pass before the ligature became the general and predominant method. His examples of syphilis were a notable contribution to the history of this grievous and in those days terrible pestilence. He believed it to be transmissible on clothing and the like. For wounds Fabry favoured a simpler surgery, but he was no little of a galenist and refused to follow Würtz in the repudiation of pus. He cannot be

ranked with the far-seeing men who once more advocated healing by first intention. And in the third quarter of the nineteenth century, in my callow days as a physician, the apothecary of a large hospital showed me a row of amputations, with stumps pouring out pus in cataracts upon the cushions, and exclaimed—"That, sir, is what I like to see; nothing so wholesome in a wound as a good discharge of laudable pus." As a university graduate,—for as universities were then we knew nothing of surgery,—I assented in superior ignorance.

England, if by England in the Middle Ages we mean no more than the Isles of Britain, made no progress in medieval or early renaissance Medicine. The Wars of the Roses may have been too savage for surgery. It was the misfortune of England, by whose surgeons in the nineteenth century Medicine was to be regenerated, that until the seventeenth century her master surgeons were few and insignificant; before Wiseman indeed, it were hard to find one worthy to rival even the slender merits of Arderne and Gale.¹ Oxford and Cambridge, as they took their origin, took their fashions from Paris; Linacre and Caius were strongly humanist in bent;²

¹ If Italy while mistress of the formative arts produced great surgeons, does the poverty of England in these arts illustrate its defects in surgery, until both arrived with Hogarth and Reynolds, Cheselden and Hunter.

² It is fair to add that Caius was more than a humanist. He wrote an important treatise on the Sweating Sickness, and was a professed teacher of anatomy. Dr. Venn says that Harvey pretty surely attended the dissections of Dr. Grimstone in Caius College.

and thus in England the division of the house of Medicine into surgery and physic became as deep and more abiding than in France; so deep and abiding that the evil of it is still at work among us.¹

Arderne was probably a better surgeon than Gilbert, or John of Gaddesden; but he is little more than a name. Nor after Mondeville, Guy, Paré, Würtz, or Maggi, is it very interesting to peruse Thomas Gale (1507-1586?). From Gale's pages however we learn how deplorable was the state of military surgery even in the constructive time of Henry VIII. Tinkers, cobblers, sowgelders, are not the worst of the words he applies to the army doctors. So terrible were the deaths and tortures under their hands, that better men were demanded; and of these was Gale, who on arrival at Montreuil found the wounds dressed with filth fit only for horses' heels. Like Würtz and Paré, Gale wrote in the vernacular, and like them again seems to have been a high-minded and gentle person. His *Certaine Works of Chirurgerie* was published in London in 1563, a stout duodecimo in Black Letter with a few rude woodcuts.² To each of the four

¹ In the days of my graduation in my own University, since eminent in Surgery, we were not examined in Surgery. We were only called upon to produce a certificate of having attended a course of lectures on Surgery and Obstetric Medicine, certificates which I suppose I produced, though I have no remembrance of the lectures. In examination indeed Surgery was expressly excluded, for the requirement was "The medical treatment of surgical and obstetrical disease." During the time of my studentship at St. George's I believe I never entered a surgical ward. Happily when I settled at Leeds I was instructed in these matters under the second Wm. Hey and the two Teales.

² Copies are in the libraries of Cambridge University and Caius College.

parts of which it consists there was a separate title. The "*Wounds made by Gonneshot*" is the third part, and here lies Gale's chief merit, that he withstood "the gross error of Jerome Brunswicke and John of Vigo, that they make the wound venomous."¹ For this independent opinion I think he deserved mention by Haeser. Gale is wise also in advising that if a ball has so entered the body that there is much difficulty in reaching it, it be left there rather than "cause mortal accidents" by the surgeon's ferreting after it. Eleven soldiers shot in the body, and thus let alone by him on service in 1544, did well.

For the rest Gale is sadly galenical,² and his pages are stuffed with unguents and other receipts. Like many of the elder surgeons he had a styptic of his own, which he honestly publishes. I regret to say he was no "first intention" man, but would put his salves even into green wounds, a surgery Sir Thomas Browne was unwilling for his charity's

¹ The title runs thus:—An excellent treatise of wounds made with gonneshot, in which is confuted both the grose error of Jerome Breunswicke, John Wiga, Alfonse Ferrius, and others: in that they make the wounde venomous, which commeth through the common powder and shotte: and also there is set out a perfect and trewe method of curying these woundes, newly compiled and published by Thomas Gale, Maister in Chirurgerie. Printed at London by Rowland Hall for Thomas Gale 1563.

² Galen, like Aristotle, was dressed as a counterfeit in distorted and conventional forms. In a dialogue prefixed to the volume, a dialogue which in scene and temper and even in expression is curiously like Isaak Walton, John Yates says he has read "Theodoricus, Brunus, Lanfrancus, Rolandus, Rogerus, Bartilpalia, Wilhelmus, Guido, Brunswicke and Vigo"—an excellent list. Gale replies "What part of Hippocrates, Galene, Avicenne, Paulus, Rhasis, Albucasis, and Haliabbas have you rede? thees be of greter authoritie."

sake to disparage in the good Samaritan; though in this case the wine may have converted it into a less improper medicine. There is no resisting the truth that hitherto the land of Harvey, Sydenham and Wiseman had not done much for any part of Medicine.¹ The great Elizabethan glory shed little of its light upon our profession. Even in the seventeenth century Harvey was a maker of physiology rather than of Medicine, and in surgery Wiseman was a bridge of one plank between the Stuarts and the great eighteenth century school of Cheselden, Pott and Hunter.

Amid the English barbers of the fourteenth century some members took the name of Barber Surgeons,² and it was in their ranks rather than in the universities or the College of Physicians³ that, as we have seen, surgery was likely to be advanced; in technical education indeed the London barbers were rather active. Moreover in England, as elsewhere, the post of King's Barber was one of much influence and profit. If we may judge by Holbein's picture, many of the leading barber surgeons were men of dignity and intelligence. Not a few of them, as in 1595 the College of Physicians com-

¹ To a little quarto by John Halle, published in 1565, with a portrait of the author, I may allude, but it seems to be no more than a translation of Lanfranc's *Chirurgia Parva*, with an appendix on the current anatomy, and an expostulation against the beastly abusers of chirurgery and physick.

² They were denoted as "Barbers exercising the faculty of surgery." There was an unincorporated and, in numbers at any rate, an insignificant body or guild of surgeons, not well disposed of course to the Barbers; and thus by divisions the cause of surgery was weakened.

³ In the sixteenth century the London College of Physicians deliberately avoided its privileges in surgery.

plained, tried "the lenity and sufferance" of this body by practising some physic. The Barber Surgeons were incorporated by Charter in 1462, and thereby obtained in London power of examination, of suspension of practitioners whether home or foreign, and of inspection of drugs. Moreover towards the end of the fifteenth century, by a policy too enlightened to last long, a sort of conjoint board, with a more or less shadowy guild of surgeons, was established for these ends. Yet in the sixteenth century this promise and privilege faded; and "all the king's subjects having knowledge or experience of the nature of herbs whether obtained by regular study or by divine favour, recovered the right of ministration to any outward sore or wound according to their cunning." Indeed in 1540 the unincorporated company of surgeons was merged in the Barber Surgeons Guild, to which the power of licensing surgeons was restored; and the bodies of four malefactors a year were assigned to the Guild. In that year also my own Chair of Physic was founded, but unhappily without this valuable endowment.

Of Spanish surgery in the sixteenth century I know nothing of my own reading: Haeser speaks of it as progressive, both in the simplification of wound treatment, and of apparatus. Three Spanish surgeons of this century are said to have claims of priority for the method of healing by first intention; namely, by cleansing, exclusion of the air, and the use of

drying and "conglutinating" dressings. When such claims were made again in the seventeenth century the claimants were referred to these Spaniards. Into the justice of this cause I have made no inquiry, for I need not repeat to you that any such claims must be put very much farther back.

Time will not permit me to dwell upon renaissance surgery by any narration of the large advances of surgery in Italy during the latter half of the sixteenth century. I can dwell no more on Vesalius than to remind you that he was surgeon as well as anatomist; and, in common with his great contemporaries Fallopius, Ingrassias, and Fabricius, did much to reduce the use of the cautery and to improve the method in amputations. Biondo of Venice in the same period protested against the mistrust of water on wounds, and used free irrigation; as Humphry was doing in my student days, before Lister's discoveries. The names of Maggi and Botallo I have mentioned already. Maggi's work on gunshot wounds was published, on his death in 1552, at Bologna; thus really coinciding with if not anticipating Paré's opinions; moreover, as I have said, they were attained by the experimental method (p. 85). The edition I used for this essay forms a part of a collection of excellent surgical treatises in a handsome folio published at Zurich in 1555.¹ The introductory research into the nature of gunshot wounds (p. 85) is admirable; and if the rest of the work be less original and too much occupied by the "concoquentia et

¹ In the Library of the Royal College of Physicians, London.

pus moventia," it is well and forcibly written and scholarly in form and completeness. A still greater surgeon who had to thank the Popes, those stiff-necked enemies of peace, for a familiarity with the lacerations of war, was Botallo, whose treatise on gunshot wounds, an excellent and exhaustive work on wounds of the head, breast, abdomen, and limbs, was published in 1560. This essay may be regarded as some compensation for his bloodthirsty and mischievous tract on Venesection in the same volume.

Now during the periods I have surveyed what were the clerks of inner medicine about? Here you will be on your guard against the sinister ways of the man with a moral; for it is my moral that physic was sterile in proportion to its divorce from surgery: yet, in the time allotted to me, if I may illustrate this theorem I cannot prove it. Happily we have Sydenham's summary of the matter, to Blackmore who asked what book on medicine he should read? "*Don Quixote*," was the answer: as if to say,— "contemplate medicine, that ponderous fantasy, in a gentle, pathetic, and ironical spirit; be tender with it as human endeavour, yet recognise it for the baseless and insubstantial fabric that it is." That the life of surgery from the thirteenth to the sixteenth century was comparatively vigorous we have just seen; but it were an ungracious task to ramble through physic only to illustrate its chimeras. A perusal of the first 200 pages of the excellent John Freind's *History* would suffice. I think no

historian will deny that in those ages medicine, in the narrower sense of this word, was a painted effigy — hollow, turgid and reactionary. Until we reach the first treatises on Epidemics, as for example Fracastoro¹ on syphilis and typhus, and the Spanish physicians on diphtheria (garotillo),² it is hard to discover in “pure medicine” any vitality, clinical or scientific, unless it lurked in the Aristophanic scepticism of Guy Patin, in the chemical therapeutics of the elusive Basil Valentine and of Paracelsus, or in the foggy platonism of Cardan. Even the staple of it was intimately entangled in astrology, alchemy, fantastical humoralism, urinoscopies and sphygmoscopies, and other dialectical puerilities. Pharmacy was, it is true, purged of some of its grossest, loathsomest, and foolishlest ingredients; and the champions of mercury and antimony climbed over the dialectical fence under a deadly fire from Paris: but it was by surgery, then the laboratory of Medicine, especially by the large and manifold surgery of war, that medicine was regenerated; and by such handicraft as that with which Harvey laid bare the secret of the circulation, and dealt the last blow to the crumbling carcass of galenism.³

¹ Fracastoro may be regarded as the founder of the doctrine of Infection. A collection of many treatises on syphilis was published at Venice in 1567, fol. It contains Maggi's treatise of 1550. Galen is quoted three or four times in each of these tracts as an authority on the French pox.

² Thus Dr. Payne says that the strong points of Gilbertus Anglicus were his account (evidently at first hand) of the plague; and also of variola and morbilli.

³ We know that Harvey was but too familiar with the battlefield; and, if we do not know that he operated upon the wounded,

One episode of inner medicine, however, I will select to serve as an example of the state of this side of our craft, namely, the schism on the place of venesection; a schism which had a far-reaching effect in the discomfiture of conventional galenism. The heresy was as follows:—the Arabs, on purely conjectural grounds, had always taught that bleeding should be derivative, practised, that is, on the side away from the lesion, or even in some limb far away from it. In the common case of pleuro - pneumonia, for example, bleeding was practised on the arm opposite to the side of the pain. Now Brissot, a learned Professor of Paris, and one conversant with the Hippocratic treatises, proclaimed in 1514 that bleeding should be practised on the same side as the disease; in order, as he said, to remove directly thence the fouled blood, and to attract the good. A strife ensued, of proportions which to us seem incredible. Parliament stretched out its arm to suppress Brissot, and at length banished him; but the war still raged, a war against the arabists which surged even to the foot of the throne of Charles V., who proclaimed Brissot to be as infamous as Luther. Clement VII. himself joined in the fight; and one far

we know that in times of peace he operated both as surgeon and obstetrician. Dr. Robert Willis in his *Life of Harvey* (Syd. Soc. 1847) makes the amazing statement that surgery in the seventeenth century "had not shown any good title to an independent existence. The surgeon of those days was but the hand or instrument of the physician . . . though Harvey it seems did not feel himself degraded—(as Dr. Willis might have supposed?)—by taking up the knife or practising midwifery" (pp. xxvi.-xxvii.). As Dr. Willis was librarian to the College of Surgeons all this may be "writ sarcastic."

greater than Clement, namely Vesalius. It so happened, however, that in the midst of the fray a kinsman of the Emperor died of pleuro-pneumonia; and the rumour grew that he had been bled in Arab orthodoxy. Thus all was thrown into confusion; the judgments of Bologna and Clement died on delivery, and, while many of Brissot's followers proceeded to drop bleeding altogether, Botallo and his school turned vampire. Servetus was against the arabists, whose hair-splitting pulse and urine lore was falling at last into discredit; and even pus itself got into some disgrace. At length, towards the end of the century, after all this clamour, it became generally admitted that Hippocrates himself bled on the side of the disease. Thus the orthodox who had disdained an intimate occupation with nature as common and unclean, and who augustly, confidently, and superciliously had been entertaining heresy for centuries without knowing it, were put to confusion. When the sticks are dry, when men's minds are prepared for a revulsion of opinions, a small crisis may have great issues; and so it was with this bitter venesection controversy. We might suppose indeed that when reigning creeds have to submit to such rebuff they cannot last long; yet, as it is far easier to preach than to think, men clung desperately then, as they cling still, even to the very skirts of them.

No better example, though of a little later date, of the stupifying effects of obsequious scholarship can be offered than that of Cæsar Magati. Magati,

a Professor of Ferrara, was by no means a pedant or a dry-as-dust. He was a man of considerable parts, who might have appealed more directly to a large personal experience; and had he relied upon himself would have been a far more interesting man than he now appears. Out of his own observation and intelligence he contributed no little to the simpler and cleaner treatment of wounds, a subject on which he published—in Venice (1616)—a handsome book; too handsome indeed, for not content with his own counsels and proofs, for which his elegant Latin is almost too fine a garment, he must needs display his learning, or cajole his readers, by incessant quotations from the ancients. Page after page, and many times upon a page, he hides himself under authority, or adorns himself with antique frippery. Two or three chapters are occupied in an attempt by glosses to warp Hippocrates and Galen towards his own opinions. Thus even in the seventeenth century this scholastic sequacity still tormented the books, those especially which issued from the universities. How well Magati could have spared this otiose labour may be perceived from such a passage as this, in protest against the incessant interference of the galenists:—"The more frequently a wound is opened up, the more frequently it is disturbed (*interturbatur*), and nature is distracted from her proper office." He protests also against the prevalent notion that wounds may be healed too soon, as even nowadays some of us suppose of an eczema. And not rarely he says such wise things as this:—"Scientia est quae opus

facile reddit, ignorantia vero difficile"—would that an introduction of this maxim into the heads of statesmen of our own time could be added to the "triumphs" of modern surgery!

The physicians of the later sixteenth century who, as practitioners of internal medicine, can be readily named as profiting by the advances of the ancillary sciences are very few. Of them were Jean Fernel (1485-1558), Professor of Medicine in Paris, and the eminent follower of Vesalius, the Basel anatomist Felix Platter (1536-1614). Fernel was one of the early explorers of the seats of disease. He distinguished the causes from the processes, placing the diseases in the solid parts, and their causes in the blood; symptoms he regarded as functional perversions. He endeavoured, as Broussais did some three centuries after him, to trace the specific fevers to definite local origins. Platter on the same lines achieved even more. These two physicians did much to establish or rather to restore "solid pathology," as opposed to the humoral. Vigorous antagonists of galenism on the same lines, though smaller men, were Giovanni Argenterio (1513-1572), and Laurent Joubert, the renowned and high-minded Chancellor of Montpellier, physician to Catherine of Medici. Joubert (1529-1583) laid much emphasis on natural causes, on physical laws, and on obedience to nature. But in this department of Medicine such men laboured in vain, except as champions of a new order. Their followers, such as Jerome Cardan, the dogmatist of "contraria contrariis," of whom Haller said "sapienter nemo

quum sapit, dementior nullus ubi errat," bitten by neoplatonism, abandoned themselves to the building of card houses ("speculative Prunkgebäude" as some one has put it), and were lost to Medicine and to science.

With the sixteenth century my survey must end: from this time Medicine entered upon a new life; upon a new surgery founded on a new anatomy, and on a new physiology of the circulation of the blood and lymph. These sciences, thus initiated, not only served surgery directly, but indirectly also, by the pervading influence of the new accuracy of observation and the enlargement of the field of induction, modified the traditional medicine of physicians unversed in methods of research, as we perceive in the objective clinical medicine of Sydenham, who was no ardent friend of the ancillary sciences, and of Boerhaave. Physiologists tell us that destruction is easy, construction difficult; but in the history of medical dogma this truth finds little illustration. So impatient is the speculative intellect of the yoke of inductive research, so tenacious is it of its liberty of prophesying, that no sooner did Harvey, by revealing the mechanics of the circulation, sap the doctrines of the schools, than some physicians instantly set to work to run up a scheme of iatro-physics; others to build a system of iatro-chemics, but upon Von Helmont rather than upon Willis and Mayow, while Hoffmann and his school resuscitated the *strictum* and *laxum* syllogisms of the Greek Methodists.

Fortunately for the seventeenth century those

busy schoolmasters, the fingers, were making their way into medicine by other than surgical routes; and by the physics of Galileo, by the anatomy of Vesalius, by the experimental physiology of Harvey, by the pathological scalpel of Morgagni, and by the chemistry of Mayow, had built into its structure some solider stuff. Yet even in the seventeenth, eighteenth and early nineteenth centuries English physicians worked still aloof from such men as Cheselden (the friend of Mead), Pott, Hunter, the Bells, Hey, Astley Cooper, and Brodie; an alienation made absolute by the establishment of the College of Surgeons, separate from the College of Physicians, in 1798, whereby the integration of Medicine in unity was once more defeated, and is still prevented, in spite of Lister, and of the masterly disciples of Lister, who in the obscure diseases of the abdomen and pelvis are doing no less intimate a service for inward medicine than Avenbrugger and Laennec had done in those of the chest.

In this sketch of the past, a sketch necessarily indiscriminate but not, I trust, indiscreet, we have seen that up to the time of Avicenna, medicine was one and undivided; that surgery was regarded truly, not as a department of disease, but as an alternative treatment of any disease which the physician could reach with his hands; that the cleavage of Medicine, not by some natural and essential divisions, but in arbitrary paltering to false pride and conceit, let the blood run out of

both its moieties; that certain diseases thus cut adrift, being nourished only on the wind, dried into mummy or wasted in an atrophy, and that such was medicine; while the diseases which were on the side of the roots, if they lost their upper sap, were fed from below, and that such was surgery.

Thus the physicians, who were cut off from the life-giving earth, being filled with husks and dust, became themselves stark and fantastic. Broadly speaking, pathology until the seventeenth century was a factitious schedule, and medicine a farrago of receipts, most of them nauseous, many of them filthy; most of them directly mischievous, all of them indirectly mischievous as tokens of a false conception of therapy. A few domestic simples, such as the laxatives, were indispensable; for the rest we are tempted to reflect that mankind might have been happier and better if Dioscorides had been strangled in his cradle.

This is the truth I have tried to get home to you:—That in the truncation of medicine the physician lost not only nor chiefly a potent means of treatment, he lost thereby the inductive method; he lost the only laboratory at his service; he lost touch with facts; he deprived his brains of the co-operation of the subtlest machine in the world—the human hand, a machine which does far more than manufacture, which returns its benefits on the maker with usury, blessing both him that takes and him that gives.

Pure thought, for its own sake, especially in early life when the temptation to it is strong and

experience small, seems so disinterested, so aloof from crude utility and temptation of gain, that in the history of ideas the construction of speculative systems has played but too great a part, and occupied but too many minds of eminent capacity. We are bound to assume that these speculations have served—and for aught we know may still serve—some good end. It seems “unhistorical” to suppose that age after age men have busied themselves to build up these vast systems in idle exercise. That nature is wasteful we know but too well; yet she is wasteful by the way, not in the main direction of her work. If some of her seed falls on stony ground, if her rain falls on the just and on the unjust, yet in the main the sowing and the rain are fruitful and joyful. Peradventure, in our modern conviction of the efficiency of the experimental method, we may be too ready to denounce methods alien to us but which, hard as it is for us to conceive, may yet play some lasting part in evolution. In our own day and fashion may we not become even too analytical; on our good side may we not be too exclusive? In the pale hue of inductive analysis, sick with too much deliberation, may we not lose resolution, overlook the concrete, and forget that if by any mode of generalisation we lose the individual in the type, and the concrete in the negations and eliminations of abstraction, we ourselves may fall by another route into the very error of the school-authors? If their search for entities was false, may there not be a sort of imposition in “laws”? When in the last analysis we attain to

unresolved axioms may we not err in calling ourselves "synthetic philosophers," in giving even to a true residuum too solid a significance? An abstraction is an abstraction, whether it be a summation of phenomena or a speculative vision; and abstractions may carry us a long way from life, from nature, and from action.

In the minds of academical teachers the notion still survives that the theoretical or university form and the practical or technical form of a profession or other calling may not only be regarded separately, and taught in some distinction—which may be true, but in independence of each other; nay, that the intrusion of the technical quality by materialising tends to degrade the purity or liberality of the theoretical; that indeed, if he have not to get his daily bread, the high-minded student may do well to let the shop severely alone. Thus the university is prone to make of education thought without hands; the technical school, hands without thought; each fighting shy of the other. But if in a liberal training the sciences must be taught whereby the crafts are interpreted, economised, and developed, no less do the crafts, by finding ever new problems and tests for the sciences, inseminate and inform the sciences, as in our day physics have been informed and fertilised by the fine craft of such men as Helmholtz, Cornu, and Stokes; or biology by that of Darwin, Virchow, Pasteur, and Lister. At the commemoration of Stokes in Westminster Abbey, Lord Kelvin honoured in him the "combination of technical skill with intuition"; and

Lord Rayleigh admired in him "the reciprocity of accurate workmanship and instinctive genius"; appreciations no less true of the distinguished speakers themselves. If it be true, as I have been told, that the University of Birmingham has a coal mine upon the premises, I anticipate that the craft of coal getting, by carrying practice into thought, will fortify the web of theory.

There exists no doubt the opposite danger of reducing education to the narrow ideas and stationary habits of the mere artisan. By stereotyped methods the shopmaster who does not see beyond his nose may cramp the prentice; and the prentice becomes shopmaster in his turn. If in the feudal times, and times like them in this respect, manual craft was despised, and the whole reason of man was driven into the attenuated spray of abstract ingenuity, in other times or parts of society a heavy plod of manual habit has so thickened "the nimble spirits in the arteries" that man was little better than a beaver: on the one side matter, gross and blockish; on the other, speculation vacuous of all touch of nature. We need sorely the elevation, the breadth, the disinterestedness, the imagination which universities create and maintain; but in universities we need also bridges in every parish between the provinces of craft and thought. Our purpose must be to obtain the blend of craft and thought which on the one hand delivers us from a creeping empiricism, on the other from exorbitant ratiocinations. That for the progress and advantage of knowledge the polar activities of sense and

thought should find a fair balance and an integration of function, is set forth judicially enough in modern philosophy, and is eminent in great examples of mankind. Moreover, it is apprehended in the reciprocal tensions of faith and works, of hypothesis and experience, of science and craft, and so forth. In our controversies on theory and practice, on universities and technical schools, on grammar and apprenticeship, we see their opposite stresses. The unison is far from being, as too often we suppose, one merely of wind and helm, it is one rather of wind and wing; it consists not in a mere obedience of hand to mind, but in some mutual implication, or generative conjugation of them.

“Nor soul helps flesh more now than flesh helps soul.”

How these two functions should live in each other we see in the Fine Arts—in the swift confederacy of hand and mind in Dürer, Michael Angelo, Rembrandt, Velasquez, Watteau, Reynolds, Watts. Genoa, Florence, Venice, Japan never disdained the crafts. The infinite delicacy of educated senses is almost more incredible than the compass of imagination. When they unite in creation no shadow is too fleeting, no line too exquisite for their common engagement and mutual reinforcement. The craft of Verrocchio becomes the magic of Leonardo da Vinci. Leonardo and Michael Angelo, in genius perhaps the greatest craftsmen the world has seen, were as skilful to invent a water engine, to anatomise a plant, or to make a stone-cutter's saw, as to paint the lineaments of the soul, and to

build the dome of St. Peter above the clouds of Christendom.

Solve the problem as hereafter we may, now we can take heed at least that energy shall not accumulate about one pole or the other. Our little children have a message to us if we would but hearken to them. Every moment they are translating action into thought and thought into action. Eye, ear, and hand are incessantly on the watch and in pursuit, gathering incessantly for the mind the forms of thought which as rapidly issue again in new activities. As we mature we gain indeed in power of restraint, but it is not that we shall cease to act, that the mind shall depose the hand; but that these variables shall issue in richer and richer functions. If we forget the hands, the cunning loom which wove our minds, if thrusting them into our pockets we turn our eyes inwards, will our minds still grow true? That by virtue of the apposable thumb, monkey became man is no metaphor; in its measure it is sober truth. The bane of our profession for the last millennium has been too much thinking; we have actually made it a point of honour to ignore the hands out of which we have grown, and in this false honour to forget that the end of life is action, and that only by action is action bred. While we profess to admire Bernard Palissy (whose lectures Paré attended) or Jean Goujon, the medieval masons or the medieval goldsmiths, we act nevertheless as if fine arts only are honourable, and mechanical arts servile; whereby we blind ourselves to the common

laws of growth, which, knowing no such distinctions, deal out barrenness to those who make them. We begin even with our children to wean them from the life of imaginative eyes and of thoughtful fingers; and, instead of teaching them to rise from simple crafts to practical crafts, to scientific crafts, or to lovely crafts, and thus to pursue the mean of nature herself, we teach them the insolence that, except in sports, the mind should drop the acquaintance of the hands.

Shall we wonder then that in this generation bold men call English people stupid; all stupid save those few men of genius or rich talent who, like Gilbert, Harvey, or Darwin, were great enough to be true to eye and hand, and to breed great conceptions by their intimate coition with the mind? Shall we wonder then that Medicine fell into sterility when by most unnatural bonds surgery, her scientific arm, was tied behind her, when she was too squeamish for raw truth, when she turned her sight inwards from lusty nature to formulas? Shall we wonder that even in the eighteenth century, when Medicine had begun tardily to occupy herself in the crafts of pathology and chemistry, one visionary after another, striding in long procession athwart the barren wilderness of physic, still wasted his generation in fastidious evasion of the things that happen, and in vain pursuit of vacuous unities! Happily, if to the high stomachs of our medieval forefathers surgical dabbings were common and unclean, still there remained some eyes curious enough and some fingers dexterous enough to carry

the art back to the skill of Hippocrates and forward to the skill of Lister ; and by the mouths of barbers and cutters, rather than of the pharisees of the colleges, Medicine breathed her lowly message to her children.

WE are requested by the Congress of Arts and Science of St. Louis, 1904, to append brief lists of the more important works on our respective subjects. The chief part of my Address was founded upon a study—virtually in all cases—of the original works of the ancient writers themselves, and upon a number of short monographs and other articles—many of them in periodicals—the titles and references of which it would be difficult now to collect; and the list would be a long one. I append a list of the more comprehensive works to which I am indebted:—

- HAESER.—*Gesch. der Medicin.* 1875-81.
PUSCHMANN.—*Handbuch d. Gesch. d. Medizin*, 2 vols. Jena, 1902-3.
DAREMBERG.—*Hist. des sciences médicales.* Paris, 1870.
Abhl. zur Gesch. d. Medicin,¹ Ed. Magnus. Breslau, 1902 *et seq.*
HIPPOCRATIS.—*Op.*, Ed. Littré, 10 vols. Paris, 1839-61.
PÉTREQUIN.—*Chirurgie d'Hippocrate*, 2 vols. Paris, 1877.
CELSE.—*Traité de Médecin*, Ed. Védrières. Paris, 1876.
GALEN, Ed. Daremberg (two vols. only published). Paris, 1854-56.
Oribase, Oeuvres d', Ed. Bussemaker et Daremberg, 5 vols. Paris, 1851-76.
PAULUS AEGINETA, Ed. Adams, 3 vols. Syd. Soc., 1845-47.
SALICET, GUILL. DE.—*Chirurgie*, Ed. Pifteau. Toulouse, 1898.
MONDEVILLE, MAÎTRE HENRI DE.—*La Chirurgie* (Soc. anc. textes Fr.), 2 vols. 1897-98. *Ibid.*, Ed. Nicaise. Paris, 1893.

¹ The tract on the history of Antiseptic Surgery in this series was issued after my Address was delivered, and I have not yet had time to read it.
